13. SUPPLEMENTARY NOTES

14. ABSTRACT

Enhanced In situ bioremediation (EISB) can be a low-cost approach for accelerating remediation timelines at sites impacted with dense non-aqueous phase liquids (DNAPLs) such as trichloroethene (TCE) and tetrachloroethene (PCE). EISB typically relies on the addition of electron donor formulations to enhance the rate of dissolution and reductive dechlorination. Although vegetable oil is a low cost electron donor, it is typically added in excess amounts to ensure that it is distributed effectively. It has been demonstrated by Harkness (2000) that the cost of electron donor can represent up to 50% of the net present value (NPV) cost when applied using passive (i.e., biostimulation) methods. Hence, the selection of electron donors has a major implication on EISB cost.

The objectives of the field demonstration/validation (DEM/VAL) included: 1.)Demonstrate application of the PED technology at field scale, assess the ability to distribute PED within the source area and enhance biodegradation; 2.) Validate the enhanced performance and efficiency of DNAPL dissolution and dechlorination following the injection of a PED. 3.) Collect cost and performance data for the application of PEDs for source zone bioremediation and provide reliable technical data relevant to field-scale implementation of the PED technology, including documentation of the expected reduction in duration and cost of remediation of DNAPL source sites.

Acknowledgements

This project had several key contributors without whom the project would have not been a success. Carmen Lebrón, NAVFAC Engineering and Expeditionary Warfare Center (EXWC), was the Project Manager and the Lead Investigator for the effort. Geosyntec Consultants (Dr. David Major, Michaye McMaster and Cory Repta) was the prime contractor for the project and as such were responsible for all field activities. Michael Pound, Cleanup Tech Manager at Naval Facilities Engineering Command Southwest (NAVFACSW) funded the laboratory work which was completed at Georgia Tech by the research team of Dr. Kurt Pennell and Dr. Natalie Cápiro. The field work was completed at NASA Kennedy Space Center (KSC) and the project sponsor at KSC was Michael Deliz. The field program at KSC was managed by Geosyntec Consultants (Jim Langenbach, Dr. Rebecca Daprato).

Contact information for the key team members are provided in Appendix A.

Executive Summary

Introduction

Enhanced In situ bioremediation (EISB) can be a low-cost approach for accelerating remediation timelines at sites impacted with dense non-aqueous phase liquids (DNAPLs) such as trichloroethene (TCE) and tetrachloroethene (PCE). EISB typically relies on the addition of electron donor formulations to enhance the rate of dissolution and reductive dechlorination. Although vegetable oil is a low cost electron donor, it is typically added in excess amounts to ensure that it is distributed effectively. It has been demonstrated by Harkness (2000) that the cost of electron donor can represent up to 50% of the net present value (NPV) cost when applied using passive (i.e., biostimulation) methods. Hence, the selection of electron donors has a major implication on EISB cost.

Achieving high rates of biologically-enhanced DNAPL dissolution requires that electron donors be delivered effectively to achieve concentrations at the DNAPL:water interface that will sustain the growth and activity of the dechlorinating biomass. Challenges with typical electron donors, such as lactate and emulsified vegetable oils (EVO) include that they are: (1) consumed as they migrate towards DNAPL source zones by non-dechlorinating biomass; and (2) result in the establishment of dechlorinating biomass in zones of dissolved DNAPL. This location can be too far away from the DNAPL to enhance its dissolution.

Partitioning electron donors (PEDs) are electron donors that partition directly into a target DNAPL. PEDs are water soluble, hence they are easily transported to a DNAPL source zone. This property aids in their mixing throughout the source zone and maximizes contact with the DNAPL. Even at high dose rates, PEDs are slowly metabolized, which facilitates delivery without significant loss and allows efficient distribution throughout the source zone. Additionally, PEDs partition strongly into DNAPL from which they are subsequently released, providing a high percentage of reducing equivalents that can be consumed in the reductive dechlorination process close to the DNAPL/water interface, and therefore promote establishing dechlorinating biomass at this interface.

Objectives

The objectives of the field demonstration/validation (DEM/VAL) included:

1. Demonstrate application of the PED technology at field scale, assess the ability to distribute PED within the source area and enhance biodegradation;
2. Validate the enhanced performance and efficiency of DNAPL dissolution and dechlorination following the injection of a PED.
3. Collect cost and performance data for the application of PEDs for source zone bioremediation and provide reliable technical data relevant to field-scale implementation of

the PED technology, including documentation of the expected reduction in duration and cost of remediation of DNAPL source sites.

A number of qualitative and quantitative performance objectives were established in order to assess the effectiveness of the amendment and are discussed in detail in Section 3.

Technical Approach

Laboratory treatability studies were conducted to evaluate candidate PEDs for eventual field application as part of the project. Based on prior research, consideration of physical-chemical properties, material costs, and toxicity, two candidate PEDs, n-butyl acetate (nBA) and n-hexanol (nHEX), were selected for laboratory evaluation for enhanced microbial reductive dechlorination of TCE-NAPL. The experiments, conducted by Georgia Tech, included: (i) PED-NAPL Partitioning Studies to assess key physical-chemical parameters that are important for successful field implementation and included liquid-liquid equilibrium batch studies and mass transfer column experiments (abiotic columns); and (ii) Bench-Scale Treatability experiments to obtain site-specific design parameters for PED delivery, mass transfer, and enhanced microbial reductive dechlorination activity in a TCE-DNAPL source zone. These tests were designed to evaluate mass transfer of the partitioning electron donor and potential microbial activity under anticipated field conditions, and ultimately to demonstrate that the PED enhances reductive dechlorination activity and DNAPL dissolution rates. The results confirmed the strong partitioning of nBA into TCE-NAPL to support dechlorination. The results from these studies were summarized in a Final Treatability Tests report in February 2010 and published by Capiro et al., (2011).

During the treatability studies, the strong partitioning of nBA into TCE- and surrogate-NAPL suggested that a single injection of PED solution was capable of providing electron donor to support microbial reductive dechlorination far beyond the number of PVs delivered, thereby reducing the need for frequent or repeated PED injections. On this basis, nBA was selected as the PED for use in the bench scale biological treatability evaluation.

The PED technology field demonstration was conducted at a source zone (Hot Spot 1) at the National Aeronautics and Space Administration (NASA) Launch Complex 34 (LC34). At this site, TCE DNAPL is associated with a silty sand/silty clay horizon at about 42 to 48 feet below land surface (ft BLS) and TCE concentrations up to 141,000 micrograms per liter (µg/L) had been reported. The zone was amended with nBA above, within and below this low permeability horizon. In total, 34,000 gallons (gal) of nBA solution (3,000 milligrams per liter [mg/L]) was injected using direct-push technology (DPT). The solution volume was selected to be approximately 50% of the total pore volume of the target zone. The amendment zone targeted the center of the Hot Spot 1 area, where TCE concentrations were greatest, roughly corresponding with the area enclosed by the 30,000 µg/L TCE isopleth and extending beyond that by approximately 5 feet (ft) in all directions.

One or more conservative tracers were added to all PED injection fluids. Bromide was used as a conservative tracer in all injection fluids, to provide an indicator of amended fluid; the concentration of bromide would indicate the proportion of injectate in any sample. Iodide was added as a tracer only in the injection fluids introduced above the confining silty clay horizon. The iodide was used to monitor for potential migration of fluid from the upper treatment zone through the clay to the lower zone, which could have occurred as a result of maintaining a lower hydraulic head in the lower zone.

Two sweep zones, one above and one below the clay horizon were separately instrumented and operated, providing two data sets with which to evaluate the performance of the PED technology. Each sweep zone was instrumented with a single central extraction well, from which integrated groundwater samples were collected routinely to monitor the average concentration of various dissolved constituents over time. The groundwater extraction system was operated using solar power. Extracted groundwater was returned to the aquifer through a set of ten groundwater injection wells on the perimeter of the TCE plume. At each of five injection locations, a pair of injection wells was installed, above and below the clay horizon, to help create an inward hydraulic gradient and promote horizontal flow across the top and base of the clay horizon.

Each extraction well operated, at a relatively low flow rate, to maintain an inward hydraulic gradient and collect representative groundwater from the aquifer on either side of the clay horizon. The extracted groundwater was analyzed for volatile organic carbons (VOCs) to establish the baseline flux of VOCs. Once stable baseline conditions were established, the demonstration area was amended with nBA and conservative tracers (bromide and iodide) using DPT injection to deliver the amendments throughout the target zone. This approach delivered the amendment solution throughout the pore volume of the plot all at once, rather than relying on advective transport in a recirculation mode, and allowed the amendments to be preferentially delivered to the clay layer and the portions of the overlying and underlying aquifers where residual DNAPL may be present. A shut-in period, with no groundwater extraction, of six weeks followed to allow the native microbes to acclimate to the nBA and for the biomass to become established within the demonstration area. Soil and groundwater samples were collected to establish the distribution of electron donor and tracer within each zone of the demonstration area prior to starting the groundwater recirculation.

Routine groundwater samples were collected during recirculation to assess the concentrations and flux of various compounds. Comparison of concentrations (VOCs, PED, tracers) in groundwater initially and over time extracted from the central wells were used to assess the "disturbance effect" of direct injection and evaluate the quantity of nBA that was taken up by the DNAPL, sorbed or diffused into secondary porosity of the formation (where the non-aqueous phase liquid [NAPL] also likely resides). Trends in the concentrations of various dissolved constituents in extracted water over time were used to understand changes in the flux of VOCs (and amended compounds). Soil sampling was conducted before (baseline delineation) and after the demonstration area was amended, to establish mass distribution within the plots, and again

after operation was halted, to assess changes over the DEM/VAL operation and correlate these results with the observed trends in groundwater concentrations.

Both sweep zones were monitored throughout the course of the demonstration, to evaluate system performance and evaluate whether laboratory assessment data are useful to predict PED performance under field conditions. The performance was assessed in terms of VOC mass flux enhancement and compared with previous studies using typical, non-partitioning, soluble electron donors such as lactate.

Results

The performance objectives of the DEM/VAL were met. nBA, was successfully introduced to the source area using readily available direct-push injection equipment, with a few extra precautions (e.g. bonding and grounding) for handling the pure nBA. The PED was able to promote biodegradation and achieved sustained production of dechlorination products, even in the presence of 1,1,2-Trichloro-1,2,2-trifluoroethane (CFC113), which was a co-contaminant in the demonstration area. *Dehalococcoides* (*Dhc)* numbers increased. Donor longevity was assessed and donor was present (as total organic carbon [TOC] and volatile fatty acids [VFAs]) up to one year following PED injection. Even with groundwater extraction the donor concentrations were sustained well beyond the point where initial injectate volume was extracted. Tests confirmed that the PED was capable of partitioning into a TCE DNAPL.

Overall, nBA was demonstrated to be a suitable electron donor for source areas. The application was completed using conventional direct-push injection equipment. Geosyntec continues to work with commercial vendors to develop off-the-shelf PEDs that are pre-mixed for ease of application. The use of PEDs for source zone bioremediation is expected to be cost-equivalent to emulsified vegetable oil applications. Donor longevity of nBA was at least equivalent to emulsified vegetable oil applications for similar applications.

The data collected over the study indicated that over the course of extracting two pore volumes that there was an increase in DNAPL dissolution rate as evident from the mass flux of total VOCs observed at the central extraction well. Furthermore, this increase in mass flux was greater than what is typically observed in applications using soluble donor. The shift in the parent:daughter breakdown product ratio over time showed that the breakdown products made up the majority of the total VOC mass flux. The increase in mass flux and increased proportion of breakdown products indicated that there was a source of the parent VOCs in the demonstration area (i.e., residual NAPL), and that there was enhanced dissolution of the source material that was made possible by maximizing the concentration gradient between the sorbed/DNAPL VOCs and water phase.

Time-trend data for the electron donor concentrations was also monitored and compared. Donor concentrations in conjunction with dechlorination product concentrations indicated the extent of sustained biological activity. Results using nBA were compared to those from tests that used soluble donors, such as lactate; the nBA provided a longer period of activity, since it partitioned

into residual NAPL initially and then gradually became re-supplied to groundwater whereas any unused soluble donor would have migrated away from the NAPL source area.

The costs to implement the PED technology for DNAPL source zone treatment will vary from site to site, depending on the size of the site (i.e., impacted volume) and several site-specific characteristics. A cost comparison was made between the PED technology and the most comparable in situ source zone treatment technology, conventional source zone bioremediation using emulsified vegetable oil (EVO). A hypothetical site was assumed to have the following characteristics:

- Sand aquifer (30% porosity) that is 30 ft deep and underlain by a clay aquitard;
- DNAPL source zone is 40 ft wide by 80 ft long by 15 ft deep (15 to 30 ft bgs); and
- 500 kg of TCE DNAPL is present

The calculated costs assume that the DNAPL and Site were previously well characterized. The total cost using PED as the electron donor was estimated to be $571,000, while the total cost using EVO was estimated to be $679,000. The differences in overall cost are attributable to the cost of donor applied in each event (which is a function of the unit cost and amount of donor required; the estimated number of applications is the same in both cases) and the duration of the remedy, which governs the number of monitoring events.

Limitations

The main limitations of using the PED technology are:

- Requires characterization - Similar to any source remediation technology, understanding and identifying of the extent of the source zone is required to estimate the DNAPL mass present and thereby, minimize the zone to be treated. Such an effort would require capital cost expenditures; and

- Site characteristics - Sites lacking suitable microorganisms to ferment the PED and/or sites that have certain geochemical conditions that inhibit biodegradation of target VOCs will require bioaugmentation and/or additional remedial measures.

Benefits

As with all source treatment technologies, delivering the PED into the source area is critical. The nBA was applied to the treatment zone with conventional direct push injection technology. This project showed that the selected PED, nBA, can; (1) achieve high rates of biologically-enhanced DNAPL dissolution; (2) be easily and effectively delivered; and (3) sustain donor supply at an effective concentration at the DNAPL:water interface to promote the growth and activity of the dechlorinating biomass. The PED was water soluble, easily transported to a DNAPL source zone, and less expensive to deliver than other commercial products.

1. INTRODUCTION

1.1 BACKGROUND

EISB can be a low-cost approach for accelerating remediation timelines at sites impacted with DNAPLs such as TCE and PCE. Compared to other remedial techniques, the estimated cost reported from McDade et al. (2005) for ISB was $29 per cubic yard ($yd^3$), in comparison to $88 per yd^3 for thermal treatment, $125 per yd^3 for chemical oxidation and $385 per yd^3 for surfactant enhanced removal, respectively. McDade et al. also indicated that the lower cost for in situ bioremediation was "related to the cheaper unit cost of enhanced bioremediation amendments (electron donor)." Vegetable oil, a low priced electron donor, costs approximately $1.00 per pound (lb). Yet, although the purchasing cost is economical, the amount of electron donor applied at impacted sites greatly affects the cost and efficacy of conducting EISB. It has been demonstrated by Harkness (2000) that the cost of electron donor can represent up to 50% of the NPV cost when applied using passive (i.e., biostimulation) methods.

To achieve high rates of biologically-enhanced DNAPL dissolution, electron donor needs to be delivered, as well as sustained at an effective concentration at the DNAPL:water interface for the growth of and consumption by dechlorinating biomass. Electron donors such as lactate and EVO are consumed as they migrate towards DNAPL source zones (DSZ) by non-dechlorinating biomass. In heterogeneous geological formations containing DNAPL pools and ganglia, there's uncertainty on the efficacy of aqueous and emulsified electron donors; i.e., will the electron donor be present at the DNAPL:water interface with a concentration appropriate to achieve maximum biodegradation rates and dissolution effects. As indicated by a Department of Defense (DoD) protocol funded by Environmental Security Technical Certification Program (ESTCP) (Air Force Center for Engineering and the Environment [AFCEE], et al., 2004), typical electron donor applications have only 1 to 10% efficiency. Hence, typical applications have accounted for the loss of reducing equivalents with the addition of a five to ten times the amount of electron donor required as a safety factor. Adding high concentrations of electron donor may overcome these limitations by allowing higher concentrations of electron donor to reach the DNAPL:water interface; however, this increases the application cost significantly.

PEDs are electron donors that partition directly into a target DNAPL. PEDs are water soluble, hence they are easily transported to a DNAPL source zone. This property aids in their mixing throughout the source zone and maximizes contact with the DNAPL. Additionally, PEDs partition strongly into DNAPL from which they are subsequently released, providing a high percentage of reducing equivalents that can be consumed in the reductive dechlorination process.

1.2 OBJECTIVE OF THE DEMONSTRATION

The objectives of this field DEM/VAL were to:

1. Demonstrate application of the PED technology at field scale, assessing the ability to distribute PED within the source area and enhance biodegradation;
2. Validate the enhanced performance and efficiency of DNAPL dissolution and dechlorination following the injection of a PED; and
3. Collect cost and performance data for the application of PEDs for source zone bioremediation and provide reliable technical data relevant to field-scale implementation of the PED technology, including documentation of the expected reduction in duration and cost of remediation of DNAPL source sites.

The field DEM/VAL was conducted at the National Aeronautics and Space Administration (NASA) LC34, located on Cape Canaveral Air Force Station (CCAFS), Cape Canaveral, Florida. A TCE source area, designated as Hot Spot 1, was identified as separate and distinct from the VOC mass beneath the Engineering Support Building (ESB). This site had a TCE-NAPL source that appeared primarily to exist within/near a lower conductivity unit. Site conditions were appropriate and a suitable on-site support network existed for execution of the DEM/VAL.

1.3 REGULATORY DRIVERS

The United States Environmental Protection Agency (USEPA) maximum contaminant level (MCL) for PCE and TCE in drinking water is 5 μg/L. This concentration is considerably less than the concentrations present in groundwater at many sites throughout the United States. The MCLs for vinyl chloride (VC) and cis-1,2-dichloroethene (cDCE) are 2 μg/L and 70 μg/L, respectively. A significant number of sites have VOCs present as free-phase DNAPLs that will act as long-term sources of VOCs to groundwater. In situ technologies for treatment of these contaminants often focus on the groundwater plume and not the source of contamination. Due to the slow dissolution of VOCs from residual or pooled DNAPL source areas, as well as the slow diffusive release of VOCs from low permeability materials (i.e. back-diffusion), conventional treatments serve solely as containment technologies and require long operational periods to remove significant amounts of DNAPL. Therefore, this demonstration sought to demonstrate and validate a more cost-effective technology to remediate DNAPL source areas and meet these regulations.

2 TECHNOLOGY

The following sections provide an overview of the technology (Section 2.1) and a discussion of the potential advantages and limitations of the technology (Section 2.2).

2.1 TECHNOLOGY DESCRIPTION

Previous studies have demonstrated that many chloroethene-dechlorinating microbial species can tolerate high VOC concentrations (Interstate Technology Regulatory Council [ITRC], 2005; Amos et al., 1997). The location of the dechlorinating biomass relative to the DNAPL:water interface is controlled by (1) toxicity effects of high chlorinated compound concentrations, and (2) the concentration profiles of both the electron donor and the dissolved phase VOCs coming from the DNAPL. When the electron donor and the dechlorinating microorganisms are near the DNAPL:water interface, high rates of biologically enhanced DNAPL dissolution can result.

The concentration profile of the electron donor is controlled by the rate at which it is consumed by native microbes relative to its transport rate by diffusion and advection processes. This results in the electron donor concentration being higher in the bulk water phase, and lower near the DNAPL:water interface. In contrast, the concentrations of dissolved phase chlorinated VOCs will be higher near the DNAPL and decrease away from the DNAPL:water interface. The electron donor and dissolved chlorinated VOC concentration profiles overlap, and the dechlorinating biomass will tend to occur at locations where these concentration profiles create the optimal ratio of electron donor to chlorinated VOCs. Biomass that forms too far away from the DNAPL:water interface will not produce significantly lower dissolved VOC concentrations near the interface where diffusion forces dominate mass transfer of the VOC from the DNAPL into solution.

PEDs are electron donors that partition directly into the DNAPL. The development of the PED approach is a combination of partitioning tracer and electron donor technologies. When PED encounters free-phase DNAPL, it partitions into the DNAPL with a corresponding decrease in its aqueous phase concentration. Depending on the method of PED addition (e.g., a pre-determined mass of PED that is injected in batches, or a constant or stepped concentration delivery scheme), different breakthrough concentrations of PED at the extraction will be observed over time. Analysis of the breakthrough will indicate when the DNAPL in the source area has taken up sufficient PED to achieve the target loading. Eventually, the DNAPL-phase PED will partition back into the groundwater and provide a much higher and sustained concentration of electron donor at the DNAPL:water interface than is achieved with existing electron donor delivery methods. The outcome is the promotion of dechlorinating biomass growth close to the DNAPL, which results in sustained enhanced DNAPL dissolution rates. This approach increases the efficiency of electron donor use for two reasons: (1) it avoids loss (i.e., microbial consumption) of donor as it migrates towards the DNAPL; and (2) it reduces the consumption of electron donor in microbial processes not associated with reductive dechlorination.

2.2 TECHNOLOGY DEVELOPMENT

Various ESTCP projects have provided significant information in the development of EISB and the application of electron donors and PED in DNAPL source areas. Experimental systems and analyses developed to study DNAPL biological dissolution (ER-0008), monitor the treatment of DNAPLs (ER-1293), demonstrate bioaugmentation (ER-9914), evaluate transport of microorganisms (ER-0315), and establish the benefits of DNAPL source zone treatment (ER-1293) have all contributed to the development of this technology. Bioenhanced dissolution was recognized as having the potential to accelerate depletion of source zone mass which would then reduce remediation timeframes and costs.

The use of PEDs was evaluated as part of The Remediation Technologies Development Forum (RTDF) Source Area BioREmediation (SABRE) program. The SABRE project compared six different electron donors, including nBA acetate and nHEX, two (2) soluble PEDs in addition to EVO, for their ability to treat DNAPL source areas. Microcosm results showed that these PEDs could support reductive dechlorination at aqueous TCE concentrations up to 400 milligrams per liter (mg/L). Both of these compounds had the potential to enhance dissolution rates.

As a precursor to the field DEM/VAL, laboratory treatability studies were conducted to evaluate two candidate PEDs, n-butyl acetate nBA and n-hexanol nHEX. This work was performed primarily at the Georgia Institute of Technology (GT) and funded by NAVFACSW. These studies are described in Section 5 of this report. The results suggested that nBA would be a suitable PED for field deployment. In water, nBA undergoes hydrolysis to form acetate and n-butanol. The n-butanol can then be utilized by fermenting organisms to produce butanoate, acetate, and hydrogen. Results of these evaluations were presented in detail in the Laboratory Treatability Study Report in February 2010 (NAVFAC ESC et al., 2010).

2.3 ADVANTAGES AND LIMITATIONS OF THE TECHNOLOGY

Groundwater remediation approaches at DNAPL sites historically employed groundwater extraction and *ex situ* treatment (i.e., pump-and-treat). Unfortunately, these approaches were demonstrated to be ineffective at significantly improving groundwater quality, even after decades of continuous operation (National Research Council, 1994). As a result, remediation technologies such as EISB have received significant attention, as government and industry struggle to develop remedial approaches for source treatment that are less intrusive, more effective, and less costly. The main advantages of the PED technology over other treatment technologies include:

- Cost – PEDs material is generally inexpensive;
- Reduced risk of mobilization - Predictable impact on DNAPL density or viscosity to mitigate the potential effects on DNAPL mobilization; and

- Safety - Non-toxic or generally regarded as safe for use in food products.

The main limitations of using the PED technology are:

- Requires characterization - Similar to any source remediation technology, understanding and identifying of the extent of the source zone is required to estimate the DNAPL mass present and thereby, minimize the zone to be treated. Such an effort would require capital cost expenditures; and

- Site characteristics - Sites lacking suitable microorganisms to ferment the PED and/or sites that have certain geochemical conditions that inhibit biodegradation of target VOCs will require bioaugmentation and/or additional remedial measures.

3 PERFORMANCE OBJECTIVES

The purpose of using a PED in place of a traditional soluble electron donor is to maximize the bioremediation efficiency and improve the DNAPL dissolution rate, while minimizing implementation costs associated with the application of EISB (primarily the cost of electron donors requiring repeated application) in DNAPL source zones. As such, the quantitative performance objectives discussed below were derived to assess the PED application impact on primary parameters such as increased DNAPL dissolution (i.e. increased total VOC mass flux) and reduction in DNAPL mass. It was assumed that the application of PEDs would cost much the same as conventional donors on a per-application basis (for example, delivery using direct-push injection), hence, if PEDs were effective longer (i.e., persisting longer results in less frequent donor amendment) and/or shorten remediation time frames, it would lower overall costs. The success criteria were thus not linked directly to the cost of application; rather, costs were evaluated to confirm that use of PED results in lower operation and maintenance costs by reducing the frequency of donor replenishment and decreasing treatment duration.

The quantitative performance objective success criteria were selected to provide reasonable and measureable goals that could be evaluated with the data collected. The criteria were intended to allow the partitioning behavior of the PED to be evaluated at this site. A number of the qualitative performance objectives were selected as possible effects of PED application that might be observed but were not necessarily required for a successful demonstration. These were generally secondary objectives that were evaluated as much as possible from the collected data.

The increase in total VOC mass flux (Quantitative Performance Objective 3.8) was anticipated to be the primary indicator that the PED was working as intended. The 50% improvement criteria was somewhat arbitrary, given the large number of factors that may have impacted the observed concentration profile, but provided a target that should be distinguishable from inherent variability in the data. Likewise, the reduction in DNAPL mass objective (Quantitative Performance Objective 3.9) was selected to provide a target (50% reduction in DNAPL mass) that could be discerned. Based on the expectation of increased dissolution of the DNAPL, resulting in shorter remediation times, a reduction in operation and maintenance costs was anticipated (Quantitative Performance Objective 3.10) and be quantified in the Cost & Performance Report. A value of 25% reduction was deemed appropriate as a target for cost reduction until actual implementation data are known.

The performance objectives are summarized in Table 1. Detailed descriptions of each performance objective are given in the corresponding sections below.

TABLE 1. PERFORMANCE OBJECTIVES
Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Performance Objective	Data Requirements	Success Criteria	Results
Qualitative Performance Objectives			
Ease of implementation (Section 3.1)	• Feedback from field crew on handling and operating requirements for PED technology and time required (particularly in comparison to traditional soluble non-PED donor injection).	• PED amendment to the source area can be effectively achieved using readily available equipment.	Confirmed. PED was successfully introduced to the source area using readily available direct-push injection equipment, with a few extra precautions (e.g. bonding and grounding) for handling the pure nBA.
Ability to promote biodegradation (Section 3.2)	• Pre- and post-amendment VOC concentrations in groundwater. • Microbial numbers.	• Increases in the concentrations of dechlorination breakdown products. • Increases in the numbers of dechlorinating bacteria.	Confirmed. • Sustained production of dechlorination products, even in presence of CFC113. Dhc numbers increased throughout both test plots.
Longevity of Electron Donor Supply (duration of remediation) (Section 3.3)	• Time of operation compared to typical application of soluble non-PED donor. • Concentrations of VOCs, nBA & n-butanol, lactate, VFA, TOC and DHG in groundwater.	• Supply of reducing equivalents is sustained for longer than a system using a non-partitioning donor, requiring less frequent donor amendment.	Confirmed. • Donor present (as TOC & VFAs) throughout 8 months (up to one year) following PED injection, declining over course of operation. Sustained well beyond the point where initial injectate volume was extracted.
PED partitions into the DNAPL (Section 3.4)	• Conservative tracer (bromide), nBA & n-butanol concentrations in groundwater following amendment.	• Reduced concentrations of nBA relative to the conservative tracer in extracted groundwater following amendment, indicating uptake by residual DNAPL. • Change in concentration should be proportional to mass of residual DNAPL present.	Confirmed. • Cápiro, N.L., Granbery, E.K., C.A. Lebrón, D.W. Major, M. McMaster, M.J. Pound, F.E. Löffler, K.D. Pennell. 2011. Liquid-Liquid Mass Transfer of Partitioning Electron Donors in Chlorinated Solvent Source Zones. Environ. Sci. Technol. 15;45(4):1547-54
PED partitions out of the DNAPL at a suitable rate and concentration (Section 3.5)	• PED concentrations in groundwater following amendment. • VFA & TOC concentrations in groundwater.	• Observe sustained concentrations of nBA (and products), sufficient concentrations of electron donor to promote dechlorination, and microbial dechlorination products in extracted groundwater.	Confirmed. • Sustained concentrations of electron donor (TOC and VFAs) were observed, with production of dechlorination products. Microbial numbers also increased.
Quantitative Performance Objectives			
Ability to deliver PED into the source area (Section 3.6)	• Injection parameter data and observations from field implementation regarding ability to deliver amendments to target zone. • nBA and tracer concentrations in groundwater and nBA in soil samples following PED amendment.	• Able to deliver desired volume of PED-amended fluid to target zone in a reasonable time (subject to limitations due to geology). • Delivery of at least 75% of the target volume (33,600 gal) of injectate. • Concentrations of PED and tracer are well distributed following amendment.	Success. • Target volume and concentration of PED-amended fluid (33,600 gal) was successfully injected to the target zones. • PED and tracer were reasonably well distributed following amendment.
Increased DNAPL dissolution (Section 3.7)	• Pre- and post-amendment VOC concentrations in groundwater	• Increase in total VOC mass flux to extraction wells. • Total VOC concentrations (as parent-compound equivalents) will show greater enhancement factor than typical donor application (+50% compared with soluble).	Generally Confirmed. • Lower zone experienced an increase in total VOC mass flux to the extraction well. • Upper zone did not show an increase in total VOC mass flux to the extraction well. • Lower zone enhancement factor was in the range for a typical donor application.

TABLE 1. PERFORMANCE OBJECTIVES
Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Performance Objective	Data Requirements	Success Criteria	Results
Quantitative Performance Objectives			
Improved efficiency of electron donor utilization (Section 3.8)	• Concentrations of VOCs, nBA & n-butanol, VFAs, TOC and DHGs in groundwater.	• Quantity of dechlorination products relative to amount of nBA consumed will be in greater proportion than typically observed using traditional soluble non-PED donors.	Uncertain. • Production of cDCE is masked by existing plume. Final soils do not have nBA, so appears all nBA is in system as TOC.
Reduction in DNAPL mass in the source area (Section 3.9)	• Pre- and post-amendment VOC concentrations in soil and groundwater	• Discernable reduction in the DNAPL mass within the source area. (50% reduction in mass from PED addition).	Confirmed. • Interpolated TVOC mass in DEM/VAL plot accounting for sorption showed a significant decline in TVOC mass (77%). Soil data is sparse and cannot be used to confidently evaluate this metric.
Reduce operation and maintenance costs (Section 3.10)	• Costs for operation and maintenance, including materials, labor and analytical costs. • Time of operation compared to typical application of soluble non-PED donor, using apparent DNAPL dissolution rates to estimate remedial timeframe.	• Shorter remedial timeframe resulting from PED application (relative to non-PED donor), which will lead to reduced operation and maintenance costs. • Experience 25% decrease relative to soluble donor	Generally confirmed. • Donor addition lasted longer, with no biofouling issues, hence requires less frequent donor addition and maintenance. • Estimate of remedial timeframe is difficult.

Notes:
DNAPL – dense non-aqueous phase liquid
nBA - n-butyl acetate
PED - partitioning electron donor
TOC – total organic compound
TVOC - total volatile organic compounds
VFA - volatile fatty acid
VOC - volatile organic compound

3.1 QUALITATIVE PERFORMANCE OBJECTIVE: EASE OF IMPLEMENTATION

To increase the likelihood that the PED technology will be adopted as an approach to source zone bioremediation, it should be straightforward to implement. Ease of implementation using standard equipment and application methods is an important benefit of the PED technology.

The ease of implementation was evaluated based on the experience of field staff and the actual availability and costs of installed equipment. The success criterion for this objective is that PED amendment to the source area is effectively achieved using readily available equipment.

This objective was achieved based on experience with the actual injection of nBA (the PED) at the Site. PED was successfully introduced to the source area using readily available direct-push injection equipment. The injection contractor performed essentially standard injections with a few extra precautions (e.g. bonding and grounding) for handling the pure nBA. Field application of nBA was deemed comparable to traditional soluble donor amendment in terms of equipment, time and effort, once the field crew were educated about nBA handling.

The equipment required for the solar-powered recirculation system was also standard issue, readily available through local suppliers and assembled by technicians with training in basic plumbing techniques.

Ease of implementation using standard equipment and application methods is an important benefit of the PED technology, since this facilitates it being adopted as an approach to source zone bioremediation.

3.2 QUALITATIVE PERFORMANCE OBJECTIVE: ABILITY TO PROMOTE BIODEGRADATION

To be effective, the PED must have promoted biodegradation of the target contaminants. The reduction in contaminant mass is a function of the degree to which biodegradation was promoted in the subsurface. A new control plot was not established for the DEM/VAL, but the project used the results from a prior pilot-scale demonstration at LC34 (Battelle, 2004; Hood et al., 2008) for comparison to a soluble donor system (the previous project used ethanol). Addition of any electron donor can promote growth (biomass) which will in turn accelerate the consumption rate of donor (i.e., the donor consumption rate will vary in time and space) and as such it was not possible to statistically assess equivalent bioactivity between the prior study and the PED demonstration. Note that the goal was not to stimulate equivalent bioactivity – the prior LC34 demonstration experienced biofouling and maintenance to control biofouling was a significant cost. The goal was to demonstrate that the PED (nBA) can be utilized by the native dechlorinating microorganisms and had the ability to promote biodegradation of TCE.

The ability to promote biodegradation using the PED technology was evaluated on the basis of increases in the concentrations of dechlorination breakdown products and increases in the population of microorganisms capable of dechlorination. Reductions in concentration of the

parent compounds also contributed to the evaluation of biodegradation activity. Groundwater samples were collected prior to donor amendment to establish baseline VOC concentrations and microbial numbers; groundwater samples were then collected over time during the demonstration to monitor changes in concentration and/or microbial numbers.

Figure 1 presents the VOC concentrations and microbial enumeration (*Dhc* and *vcr*A) values obtained at the extraction wells for the upper and lower aquifer units (RW0007 and RW0008; respectively). The addition of nBA as an electron donor promoted biodegradation of TCE to less chlorinated daughter products and resulted in a substantial increase in the native dechlorinating populations.

This objective was confirmed by the increases in the concentration of degradation products (cDCE, VC and ethene) from the reductive dechlorination of TCE and increases in the population of dechlorinating microorganisms in response to PED addition. In both the upper and lower treatment zones, sustained production of dechlorination products, including ethene, was observed, demonstrating that the PED (nBA) could be utilized by the native dechlorinating microorganisms and thus had the ability to promote biodegradation of TCE.

3.3 QUALITATIVE PERFORMANCE OBJECTIVE: LONGEVITY OF ELECTRON DONOR SUPPLY

The principal attribute of the PED technology is that the supplied electron donor partitions into residual DNAPL, if present, when it is first supplied, and then re-partitions to groundwater along with VOCs as they dissolve from the NAPL-phase or desorb from solid phases, thus supplying electron donor to the NAPL:water interface where it may be utilized by dechlorinating bacteria. This property of the PED compound means that it needs to be applied less frequently, since the initial quantity amended can be designed to supply reducing equivalents for multiple pore volumes, thus decreasing the frequency of, and associated costs for repeat donor applications.

Longevity of electron donor supply was assessed using time-series groundwater concentration data, namely the concentrations of remaining nBA, donor breakdown products (including n-Butanol [nBuOH] from nBA), VFAs and TOC. Sustained donor supply from a one-time addition of PED is desirable, as it requires reduced frequency of donor replenishment.

This objective was confirmed by the persistence of electron donor equivalents throughout the DEM/VAL operation. The concentrations of nBA, nBuOH, VFAs and TOC were assessed and are plotted in time-series figures. Donor concentrations observed at the central extraction wells, RW0007 and RW0008, were assessed in terms of the amount of carbon (i.e. millimole equivalents of carbon per liter [mmol C/L]) and indicate that the measured TOC concentrations were generally equal to the sum of the individually quantified components. For example, at RW0007 the TOC concentration was, on average, 91% of the sum of the VFAs plus other carbon-containing compounds (nBA, nBuOH, VOCs and dissolved hydrocarbon gases [DHGs]) and at RW0008, the TOC concentration was 99% of the sum of the VFAs and other measured

carbon-containing compounds (Figure 2). A one-time addition of the PED was sufficient for at least one year of recirculation in the DEM/VAL scenario.

3.4 QUALITATIVE PERFORMANCE OBJECTIVE: PED PARTITIONS INTO THE DNAPL

A major feature of the PED technology is the ability of the PED to partition into residual DNAPL phases and sorb to solid-phase carbon, resulting in a decrease in the concentration of PED in groundwater. The amount of concentration change will be directly related to the amount of residual NAPL phase; however, the amount of residual NAPL present in the area is not known, so the degree of concentration change cannot be predicted. It is thus a qualitative objective to detect the uptake of the PED. The PED (nBA) is selected for its high partitioning coefficient, so that a large proportion of the PED delivered initially will become associated with residual NAPL and sorbed-phase contaminants, and be gradually released to groundwater over time as the NAPL dissolves and releases contaminants.

The partitioning of PED into DNAPL was evaluated using groundwater analyses for conservative tracers (bromide and iodide), nBA and nBuOH, and TOC following PED injection. In the Demonstration Plan, it was suggested that nBA and VOC concentrations in soil would be analysed as well, but this was deemed impractical, as it would not be possible to determine whether the nBA and VOCs were in a NAPL phase or not. Because baseline soil data for VOCs showed considerable spatial variability and the presence of DNAPL was not confirmed, it was considered infeasible to attempt to quantify nBA within TCE-NAPL through soil sampling.

Data collected in the field DEM/VAL did not have sufficient resolution to demonstrate PED partitioning into DNAPL. However, this objective was validated during the laboratory treatability tests which clearly demonstrated partitioning in the laboratory column experiments. Results have been published in Environmental Science and Technology (Cápiro et al., 2011). The major reason for the apparent difference in behavior was the amount of NAPL present in each case. As discussed in the Demonstration Plan, the change in the aqueous concentrations of nBA should be proportional to the mass of residual NAPL present. In the laboratory column tests, the emplaced NAPL zone occupied 10-15% of the pore space. At this relatively high saturation, the NAPL phase can sequester a significant amount of nBA, resulting in a relatively large decrease in the aqueous phase concentration of nBA that can be readily detected. In contrast, the DEM/VAL field plot had low residual NAPL saturation (in fact, the degree of saturation could not be determined), such that only a relatively small amount of nBA would need to partition from the aqueous phase to establish equilibrium between the aqueous phase and any NAPL phase droplets. If only a small amount of nBA was sequestered from the aqueous phase, the resulting decrease in the concentration of nBA would be small and difficult to discern in the field data.

3.5 QUALITATIVE PERFORMANCE OBJECTIVE: PED PARTITIONS OUT OF THE DNAPL AT A SUITABLE RATE AND CONCENTRATION

Ideally, the applied PED, once partitioned into residual DNAPL phases and onto sorption sites, must be released to groundwater at a rate and concentration that is sufficient to support

bioremediation. The success of the technology relies on creating a sustained donor supply that matches the release of contaminants.

Assuming that PED partitioning into DNAPL is successful, the expectation is that PED will be released back to groundwater when dissolved-phase PED concentrations decrease as the un-amended groundwater is pulled into the treatment area. The intent is that this will sustain concentrations of nBA and/or its breakdown products that are greater than would persist in a soluble donor system after a pore volume of water has been extracted. In a soluble donor system, the donor will be removed with groundwater. In the PED system, donor is re-supplied from the DNAPL phase (and sorptive sites).

Assessment of this objective required use of nBA concentrations in groundwater over time, nBuOH concentrations, VFA and TOC concentrations, and VOC concentrations in groundwater. The assessment was not straightforward, as the nBA was actively consumed as it migrated toward the extraction well; however, evidence of sustained donor supply provided by the presence of dechlorination products should also support the evaluation. Changes in the amount of DNAPL dissolution were assessed by comparing the total flux of VOCs observed at the central extraction wells before and after application of the PED.

The objective was met. Sustained concentrations of electron donor (TOC and VFAs) were observed, with production of dechlorination products. Microbial numbers also increased. Additional supporting information on this objective is provided in Section 5.7.

3.6 QUANTITATIVE PERFORMANCE OBJECTIVE: ABILITY TO DELIVER PED INTO THE SOURCE AREAS

One objective of the PED DEM/VAL was to demonstrate that the PED can be readily delivered to the source area. In order to be an effective bioremediation approach, the application of PED should have been reasonably comparable to that of other traditional electron donors, so that its other properties can provide an overall benefit. The ability to deliver the design quantity of PED into the source area was expected to be comparable to that of other electron donors.

The objective was to be considered met if the design quantity of PED-amended fluid was delivered to the target zones within a reasonable amount of time (hours), using reasonable injection pressures. The success criterion was to amend at least 75% of the target volume (33,600 gal). This objective was achieved. The injection program successfully delivered the target volume and concentration of PED-amended fluid to the target zones: 34,000 gal of injectate containing 3,000 mg/L nBA with bromide and/or iodide as tracers was injected.

An additional consideration for this objective was that the post-injection concentrations of nBA, in soil and groundwater, were well distributed following amendment. This objective was also met as evidenced by the post-injection sampling event where 11 locations were sampled and

nBA was found in all but the sampling location within the silty clay layer. Of the 10 locations with nBA, 8 had nBA concentrations in excess of 10 mg/L.

3.7 QUANTITATIVE PERFORMANCE OBJECTIVE: INCREASED DNAPL DISSOLUTION

The PED technology is designed to provide electron donor at the NAPL:water interface to promote growth of dechlorinating biomass as close to the source of dissolved-phase VOCs as possible. By promoting and supporting reductive dechlorination close to the NAPL:water interface, the PED creates a steep concentration gradient between the NAPL and the aqueous phases, which results in increased DNAPL dissolution.

The amount of DNAPL dissolution was assessed by comparing the mass discharge of VOCs before and after application of the donor. Mass discharge is an integrated estimate of the mass flux, representing the total mass of any solute conveyed by groundwater through a plane, in this case a cylindrical surface around the extraction well. One advantage of this method is that the extraction well effectively integrates flow and concentration so that even small concentration hot spots and high-transmissivity zones are captured by the well and included in the estimate (ITRC, 2010). Typically this approach requires that the pumping well not increase the flow through the source zone, which might increase the dissolution rate (concentrations may or may not change), pumping be continued long enough that relatively steady-state conditions are achieved, and capture of the high-discharge portions of the plume must be complete or near-complete (ITRC, 2010).

The mass discharge was calculated from the groundwater VOC concentration data and the pumping rate and volume data. The total amount of TCE equivalents was calculated as the sum of TCE and its breakdown products, on a molar basis. The product of these measured concentrations and the volumetric pumping rate yielded an estimate of the total mass discharge rate. Using the pumped volumes, estimates of cumulative total mass discharge over time were determined. Changes in the total amount of TCE equivalents over time indicated changes in the rate of DNAPL dissolution. Extracted groundwater was re-injected in the peripheral ring of injection wells without removing VOCs (or donor); thus, dissolved species in groundwater removed from the extraction wells were re-introduced to the aquifer at the perimeter of the sweep zones. However, to account for this, estimates of the relative amount of recycle were obtained from comparison of the pumped volumes to estimates of the sweep zone pore volume, the tracer data and the TOC data.

It was expected that the PED plot would have increases in total VOC concentrations following amendment with nBA (relative to baseline). This increase in total VOC mass flux would be a primary indicator that the PED application worked as intended. The objective was to be considered met if the increase in total VOC mass flux observed in the PED plot was 50% or greater than that typically observed at sites where soluble donor was applied.

This quantitative performance metric was met. In the lower zone there was an increase in the total VOC mass flux to the extraction well over the evaluation period. However, in the upper zone an increase in total VOC mass flux to the extraction well was not observed. The upper zone may have been affected by the presence of high concentrations of 1,1,2-Trichloro-1,2,2-trifluoroethane (CFC113), a compound that can inhibit reductive dechlorination to ethene.

Time trend plots of the VOCs at extraction wells RW0007 and RW0008 are presented in Figures 3a and 3b. Total VOC mass discharge did not increase at the extraction well in the upper zone even though there was a definite shift towards lesser-chlorinated degradation products, as illustrated by the extent of dechlorination calculation shown in Figure 4a. A number of factors may have contributed to this, including:

- Elevated concentrations of cDCE present in soil and groundwater before the DEM/VAL began obscured the effect of PED promoting degradation of TCE to cDCE;

- Sustained elevated concentrations of CFC113 could inhibit the dechlorination of cDCE, which would further obscure the quantification of the amount of dechlorination; and

- Distribution of TCE (and CFC113) was non-uniform. Most of the TCE mass was found at BW0001 and RW0007, suggesting there may have been DNAPL in that portion of the demonstration area, but not uniformly around the extraction well, so that the pumped groundwater represents a blend of water that passed through a source zone where contact with residual DNAPL was possible, and other water that came from/through other portions of the demonstration area(s) where there was little TCE NAPL to contact.

The lower zone did experience an increase in total VOC mass discharge at the extraction well. The concentration trend is presented in Figure 3b. This figure shows that the increasing total VOC mass in extracted groundwater was due to increasing amounts of TCE degradation products. This is also illustrated by the extent of dechlorination calculation shown in Figure 4b.

3.8 QUANTITATIVE PERFORMANCE OBJECTIVE: IMPROVED EFFICIENCY OF ELECTRON DONOR UTILIZATION

Since PEDs partition into residual DNAPL, and then partition back into groundwater along with VOCs as they dissolve from the NAPL-phase, the electron donor may be preferentially utilized by dechlorinating bacteria. Hence, a greater proportion of the amended PED was expected to be used to support reductive dechlorination of VOCs rather than untargeted reactions (e.g., methane production).

The efficiency of electron donor utilization was assessed using the groundwater concentrations of VOCs, electron donors, breakdown products, and DHGs over time. The parent donor compound, nBA, along with its breakdown products (nBuOH, acetate, and other VFAs), were monitored, in addition to the VOCs and their breakdown products, plus other compounds that may have formed, such as methane, so that a detailed understanding of the donor consumption pathways was ascertained.

The objective would be considered met if the 'utilization ratio' was greater for PED than is typically observed with traditional soluble donors. The success criterion would be an observed increase in utilization ratio of 50% or greater relative to the soluble donor system of the prior LC34 study (Battelle, 2004; Hood et al., 2008).

The PED lasted longer than a soluble donor. Several pore volume flushes were completed and if the donor was soluble it would have been extracted from the system. However, determining that the PED was more than 50% better than a soluble donor was not quantitatively determined. In the upper sweep zone significant cDCE was present at the start of the DEM/VAL and so production of cDCE from PED addition was not simply discerned as an increase in cDCE. This was not the case for the LC34 study. There were also elevated concentrations of CFC113 in many of the collected groundwater samples, which can inhibit dechlorination and hence limit confirmation of the objective. Nevertheless, the PED can be considered similar to other long term electron donors (e.g., emulsified vegetable oils) over the benefits of soluble donors (e.g., lactate or ethanol). Therefore, quantification of the 50% improvement of the PED over soluble donor utilization was not definitive, but we have evidence that it should be an improvement over soluble donors and possibly as effective as emulsified vegetable oil donors.

3.9 QUANTITATIVE PERFORMANCE OBJECTIVE: REDUCTION IN DNAPL MASS IN THE SOURCE AREA

One goal of source zone bioremediation is to reduce the amount of DNAPL remaining in the source area, to reduce the expected time for clean-up. Reduced source mass may also result in reduced VOC loading to the downgradient plume.

Assessment of this objective was based on the baseline and final VOC concentrations in soil and groundwater. If the PED is able to partition effectively into residual DNAPL and this promotes

bioactivity then a decrease in soil VOC concentrations should occur. This may increase groundwater VOC concentrations (in part due to production of daughter products).

Soil samples were collected from the DEM/VAL at four intervals (baseline, post-biomass growth phase and two during recirculation phase). The baseline soil samples were collected from different locations to the remaining three events. Results for each event were averaged together to develop an average soil concentration (see table below) to estimate TCE and cDCE in soils at the locations sampled. There is a decline in the amount of TCE detected over the course of the DEM/VAL, from the end of the Biomass Growth Phase to the end of the Main Recirculation Phase (Month 7) to the end of the Interim Measure Recirculation Phase (Month 13). Note that baseline is quite different because it represents a different set of locations.

Average Soil Concentrations (mg/kg)

	TCE	cDCE
Baseline	3.60	2.35
Post Biomass Growth	21.27	2.89
Post Main Recirculation Phase (Month 7)	13.07	5.83
Post Interim Measure Recirculation Phase (Month 13)	10.23	5.70

The objective was confirmed based on the interpolated VOC mass in the treatment zone assuming sorption is unchanged over the DEM/VAL. There was a significant decline in total volatile organic compound (TVOC) mass, with an estimated 77% decrease over the DEM/VAL.

3.10 QUANTITATIVE PERFORMANCE OBJECTIVE: REDUCE OPERATION AND MAINTENANCE COSTS

A major feature of the PED technology is the reduced frequency of donor replenishment (and the commensurate reduction in application costs), and the shorter remedial timeframes, resulting in lower operation and maintenance (O&M) costs anticipated due to increased rates of DNAPL dissolution. The success of the PED technology depends on the degree to which these reductions in the number of applications and in the cost of operation and maintenance can be realized.

The reduction in operation and maintenance costs was estimated on the basis of the data collected during the DEM/VAL, including the costs for materials, labor and analytical costs. The time of operation relative to operation with a soluble donor was extrapolated using apparent DNAPL dissolution rates to estimate remedial timeframe. The laboratory experiments (see Section 5.3) and the field observed longevity (section 5.7) were used to estimate the frequency of re-amendment, to estimate costs over the lifetime of the remedy.

The performance objective was generally confirmed. The PED remained longer in the groundwater compared to a simple soluble donor (e.g., lactate) and promoted dechlorination. After 8 months of recirculation there was still enough residual organic carbon to promote bioactivity. On this basis we can conclude that the donor lasted longer than estimated, with no

significant biofouling issues and hence less frequent donor addition and maintenance with the PED over a soluble donor. Given this it would be likely that the PED will provide a shorter remedial timeframe but it is not exactly known if this will be a cost savings of 25% or more. At the end of the DEM/VAL VOC mass remained in parts of the test area and the time to completely treat remaining VOCs was not known.

4 SITE DESCRIPTION

4.1 SITE LOCATION AND HISTORY

Hot Spot 1 is located at LC34 on CCAFS on the east-central Atlantic coast of Florida in Brevard County (Figure 5). The site is located east of the former ESB as shown on Figure 6. Prior to development, LC34 consisted of relict sand dunes and interdunal swales typical of barrier island depositional environments.

A full description of the site history, operations, investigations, and analytical results is detailed in the Resource Conservation and Recovery Act (RCRA) Facility Investigation (RFI) Report (NASA, 1999), RFI Addendum Report (NASA, 2003), and the Corrective Measures Study (CMS) Report (NASA, 2007).

The launch complex was designed to support NASA's Saturn 1 and Saturn 1B program during Project Apollo. Construction started on LC34 in June 1959, and NASA accepted the site from the contractor in January 1962. Four Saturn 1 and three Saturn 1B vehicles were launched from LC34 between 27 October 1961 and 12 October 1968. Launch operations at LC34 included the storage, transport, and use of nitrogen, helium, liquid oxygen (LOX), RP-1 fuel (modified kerosene fuel), liquid hydrogen, hydrazine, and nitrogen tetroxide. Helium was used as a mixing agent in the LOX tanks of the booster rockets. Nitrogen was used for purging fuel and LOX lines, isolating engine and instrument compartments, and operating certain pneumatic components. RP-1 and LOX were used to fuel the Saturn rockets, and hydrogen, hydrazine, and nitrogen tetroxide were used aboard the various spacecraft for steering purposes. Historical records suggest that workers flushed rocket engines on the launch pad and conducted precision cleaning of spaceflight hardware in the ESB with TCE. A significant amount of solvents were likely disposed of into drains within the ESB and a grated trench system, located adjacent to the northwest side of the ESB that discharged to the sandy soil outside of the ESB. No records regarding the quantities of TCE used at the site were available.

Following the launch of Apollo 7 in 1968, the Complex was held in standby status for possible use in the Skylab program. The launch complex was taken out of service in November 1971, and the service structures along with operational equipment were scrapped in April 1972. However, the majority of the on-site buildings and structures were abandoned-in-place. Native and invasive vegetation and trees overgrew the majority of the site, with dense, wooded areas surrounding the site. The Complex was declared part of the Man In Space National Historic Landmark in 1984. NASA retained ownership of the Complex until 1994 when the land and structures were given back to the Air Force with the exception of the ESB. NASA continued to use this facility as office space until 1998 when remediation pilot demonstrations were initiated.

Previous investigations (RFI and CMS activities) indicated that the principal groundwater contaminants at LC34 included TCE and its dechlorination products, cDCE, *trans*-1,2-dichloroethene (tDCE), and VC. These impacts were caused by a significant release of TCE in the area of the ESB during the operational period from the late 1950's to 1968. It is estimated that mass remaining under the slab of the former ESB building is approximately 90,000 lbs of TCE. The groundwater impacts of VOCs present at concentrations exceeding their Groundwater Cleanup Target Levels (GCTLs) encompass an area of approximately 330 acres and extend from approximately 15 to 80 ft BLS. In the CMS (NASA, 2007) the groundwater impacts were categorized as follows (Figure 6):

- the DSZ: The DSZ includes the area within a "box" which encompasses the 100 milligram per kilogram (mg/kg) iso-concentration contour;
- the high concentration plume (HCP): The HCP includes the area of impacted groundwater with TCE, cDCE, tDCE, and VC concentrations greater than the Natural Attenuation Default Concentrations (NADCs) and less than 100 mg/kg TCE (i.e., beyond the DSZ); and
- the low concentration plume (LCP): The LCP includes the area of impacted groundwater wherein concentrations are greater than the individual GCTL for TCE, cDCE, tDCE, and VC, and less than the NADCs.

Hot Spot 1 is a small TCE source area separate from the VOC mass beneath the ESB (refer to Figure 6 and Figure 7). The TCE plume here has been generally delineated to concentrations in groundwater greater than the Florida Department of Environmental Protection (FDEP) NADC of 300 µg/L. Below this level, delineation is complicated by the presence of the larger HCP. Similarly, the cDCE and VC contributions cannot be readily quantified due to comingling of the plumes. A probable source of the Hot Spot 1 area TCE mass has been identified as a drum storage area in an old air photo from 1969. The area delimited by the 300 µg/L TCE isopleth is about 4,000 square feet (ft^2), while the zone of greatest TCE concentration, within the 30,000 µg/L isopleth, is about 400 ft^2 in area (see Figure 12).

4.2 SITE GEOLOGY AND HYDROGEOLOGY

4.2.1 Lithology

The shallow aquifer system at the site, which includes undifferentiated deposits of Pliocene, Pleistocene and Recent Age, consists primarily of tan to gray, medium to very fine-grained sands with varying amounts of shell fragments. This lithology is present from land surface to a depth of approximately 45 ft BLS. In the vicinity of the Launch Pad Complex, which is at a higher surface elevation than the surrounding area, this lithology is present at greater depths. A very fine-grained yellowish gray to light olive gray sand stratum containing a significant amount of silt is present from approximately 25 to 30 ft BLS; this stratum is a minimum of 5 ft in thickness. The first hydrogeologic semi-confining unit (aquitard) is present at an approximate depth of 45 ft BLS and has a typical thickness of less than 1 ft to 3 ft. Abundant shell fragments overlie the aquitards, which consists of a thin layer of light brownish gray to light olive gray silty clay to clayey silt with minor amounts of sand and shell fragments. Geotechnical analyses of five Shelby tube samples of this stratum in the vicinity of the ESB reported an average vertical hydraulic conductivity of 1.67×10^{-4} feet per day (ft/day) (5.89×10^{-8} centimeters per second [cm/sec]) (NASA, 1999).

The stratum beneath the aquitard consists primarily of light gray, medium to coarse-grained sands and silts with abundant shell fragments to a depth of 60 ft BLS. This stratum is underlain by homogeneous, light olive gray, coarse to fine sands ("salt and pepper" sand) from approximately 60 to 80 ft BLS. Light olive gray to yellowish gray, silty sand to clayey sand with abundant white shell fragments are present from 80 to 95 ft BLS. This stratum is underlain by yellowish gray to light gray, fine- to coarse-grained sands with minor amounts of shell fragments from approximately 95 to 118 ft BLS. Green clay with minor amounts of sand, phosphate nodules, and limestone fragments, are present at a depth of approximately 118 ft BLS. This represents the top of the Tamiami Formation equivalent, which extends to 125 ft BLS. The stratum also consists of yellowish gray clayey sand to clay. The Hawthorn Group is encountered at approximately 125 ft BLS and consists of yellowish gray to light olive gray clayey sand to dolosilt with up to 20% phosphate. This lithology persists to at least 140 ft BLS. Geotechnical analysis of a sample from the clay stratum indicates a vertical hydraulic conductivity of 5.1×10^{-4} ft/day (1.80×10^{-7} cm/sec) (NASA, 2003). The hydrogeologic zones encountered beneath the site are presented on Figure 8.

The site geology can be summarized as follows:

- Land surface to 45 ft BLS: tan to gray, medium to very fine-grained sands with varying amounts of shell fragments, with a hydraulic conductivity of 3ft/day in the 30 to 45 ft BLS interval;

- 45 to 48 ft BLS (thickness varies): semi-confining unit comprised of silty sand to sandy clay with minor amounts of sand and shell fragments with a hydraulic conductivity of 10^{-3} to 10^{-4} ft/day;
- 48 to 60 ft BLS: medium light gray, medium to coarse-grained silty sand with abundant shell fragments with a hydraulic conductivity of approximately 2.8 ft/day (based upon pneumatic slug testing in 2009); and
- 60 to 80 ft BLS: homogeneous light olive gray, coarse to fine sands with a hydraulic conductivity of approximately 7.5 ft/day.

A continuous soil core was collected, using a sonic method, in the middle of the Hot Spot 1 area (SB1000, Figures 4 and 6). The core was consistent with general site lithology, with the exception of a second clay layer identified from 54 to 55 ft BLS; a generalized lithologic cross section of the Hot Spot 1 area based on that core is shown on Figure 4 and summarized as follows:

- Surface to 5 ft BLS was hand-cleared and thus not logged;
- 5 to 10 ft BLS: gray, tan, brown fine sand with shell fragments;
- 10 to 42 ft BLS: gray fine sand with shell fragments;
- 42 to 48 ft BLS: gray silty sand and silty clay with shell fragments;
- 48 to 54 ft BLS: gray fine sand with shell fragments and silt;
- 54 to 55 ft BLS: gray silty clay;
- 55 to 60 ft BLS: black, white gray medium sand;
- 60 to 66 ft BLS: silty, fine sand and fine sand with silt and shell fragments; and
- 66 to 80 ft BLS: gray and black medium sand with shell fragments.

4.2.2 Site Hydrology

Groundwater at the site is generally encountered at about 5 ft BLS. In the shallow island aquifer system found at LC34, surface water bodies influence groundwater flow. Two large water bodies, the Atlantic Ocean and the Banana River are located approximately 0.25 miles to the east and 1 mile west of the site, respectively. Period of record water levels indicate the primary direction of groundwater flow is directed to the coastal margins of the site with the highest recorded water levels near the area of the former ESB. At Hot Spot 1, which is south of the launch pad, groundwater flow in the shallow aquifer is predominantly to the east, toward the Atlantic Ocean. Groundwater gradients are relatively flat and in general, groundwater flow is sluggish. Groundwater elevations show some tidal influence; apparent flow reversals may occur depending on tide stage at time of groundwater gauging. Groundwater potentiometric surface maps for the shallow aquifer from the 2008 and 2009 Annual Groundwater Monitoring Reports (NASA, 2009; NASA, 2010) are shown in Figure 9.

4.2.3 Groundwater Geochemistry

Samples from selected wells at LC34, including IW0002I and IW0002D have been analyzed periodically for a suite of natural attenuation indicator parameters. Geochemical conditions in Hot Spot 1 appear to be consistent with anaerobic microbial activity, with relatively reducing redox conditions and elevated concentrations of ethane (and methane). There is about 18 mg/L of sulfate present in the groundwater. These conditions are consistent with the concentrations of cDCE and VC, which indicate that microbial reductive dechlorination is active at the site.

4.3 CONTAMINANT DISTRIBUTION

The Hot Spot 1 source mass, while a distinct source from that delineated beneath the ESB, is situated within the large VOC plume around the ESB. As a result, there are elevated levels of cDCE and VC that may not originate from the TCE in Hot Spot 1. The Hot Spot 1 TCE plume has been delineated to a concentration of 300 µg/L; below this concentration the plumes are difficult to separate on the map due to comingling of the plumes. For the breakdown products (cDCE and VC), separation is not possible. Although no other VOCs were identified in groundwater during prior routine monitoring of the existing monitoring wells, CFC113 was present at several locations in the upper aquifer at concentrations up to 130,000 µg/L.

VOC impacts in the Hot Spot 1 Area were delineated from 2008 to 2009 through a series of direct-push groundwater sampling events, a membrane interface probe (MIP) investigation, saturated zone soil sampling and installation and sampling of a deep monitoring well (screen interval of 70 to 80 ft BLS). MIP results were used in conjunction with the concentration data to define the vertical interval of VOC-impacted groundwater, which was deemed to be the 30 to 60 ft BLS interval for the PED DEM/VAL.

The CMS for the site (NASA, 2007) presents theoretical soil concentrations for TCE-DNAPL saturation; a value of about 300 mg/kg is considered representative of NAPL-phase TCE, using literature values for TCE solubility and organic carbon partition coefficient (K_{oc}), assumed values of bulk density and porosity, and measured values of the fraction of organic carbon (f_{oc}). The maximum value measured, 56.2 mg/kg^{dry}, which is equivalent to 42.7 mg/kg in the bulk, is about 14% of the theoretical threshold value.; hence, DNAPL is inferred to be present in the plot based on this result together with the groundwater concentrations.

The groundwater concentrations are indicative of a TCE-NAPL source: the source has been there for over 40 years and concentrations of TCE are still about 30,000 µg/L based on groundwater samples from the monitoring wells and DPT samples in the middle of the Hot Spot 1 area.

5 TEST DESIGN

5.1 CONCEPTUAL EXPERIMENTAL DESIGN

The objective of the this project was to DEM/VAL the application of a PED at a DNAPL source zone site to improve the biologically-enhanced dissolution rate of DNAPL over that which can be achieved with soluble, non-partitioning electron donors. The overarching goal was to demonstrate that PED application offered increased bioremediation efficiency and decreased implementation costs.

The PED technology was demonstrated at a source zone hot spot wherein TCE DNAPL is associated with a silty sand/silty clay horizon at about 42 to 48 ft BLS and TCE concentrations up to 141,000 µg/L had been reported. Figure 10 shows a cross section of the demonstration area. The hot spot was amended with PED nBA above, within and below this low permeability horizon. Two sweep zones, one above and one below the clay horizon were separately instrumented and operated, providing two data sets with which to evaluate the performance of the PED technology. Each sweep zone was instrumented with a single central extraction well, from which integrated groundwater samples were collected routinely to monitor the average concentration of various dissolved constituents over time. Extracted groundwater was returned to the aquifer through a set of ten groundwater injection wells on the perimeter of the TCE plume. At each of five injection locations, a pair of injection wells was installed, above and below the clay horizon, to help create an inward hydraulic gradient and promote horizontal flow across the top and base of the clay horizon.

Each extraction well operated, at a relatively low flow rate, to maintain an inward hydraulic gradient and collect representative groundwater from the aquifer on either side of the clay horizon. The extracted groundwater was analyzed for VOCs to establish the baseline flux of VOCs. Once baseline conditions were established, the zone was amended with electron donor (nBA) and conservative tracers (bromide and iodide) using DPT injection to deliver the amendments throughout the target zone. This approach delivered the amendment solution throughout the pore volume of the plot all at once, rather than relying on advective transport in a recirculation mode, and allowed the amendments to be preferentially delivered to the clay layer and the portions of the overlying and underlying aquifers where residual DNAPL may occur. A shut-in period, with no groundwater extraction, was then observed, to allow native microbes to acclimate to the nBA and allow biomass to become established within the demonstration area. Following this, soil and groundwater samples were collected to establish the distribution of electron donor and tracer within each demonstration area.

Figure 10

P:\CADD_Geosyntec Branch\Titusville Office\NASA\TR0272.03\0552BF01-FIG 10.dwg

Following the biomass growth shut-in period, groundwater extraction was re-initiated, with routine sample collection to assess the concentrations and flux of various compounds. Comparison of concentrations (VOCs, PED, tracers) in groundwater initially and over time extracted from the central wells will assess the "disturbance effect" of direct injection and evaluate the quantity of PED that was taken up by NAPL, sorbed or diffused into secondary porosity of the formation (where the NAPL also likely resides). Trends in the concentrations of various dissolved constituents in extracted water over time were used to understand changes in the flux of VOCs (and amended compounds). Soil sampling was conducted before (baseline delineation) and after the demonstration area was amended, to establish mass distribution within the plots, and again after operation was halted, to assess changes over the DEM/VAL operation and correlate these results with the observed trends in groundwater concentrations.

Both sweep zones were monitored throughout the course of the demonstration (March 2011 to February 2012), to evaluate system performance and evaluate whether laboratory assessment data are useful to predict PED performance under field conditions. The performance was assessed in terms of VOC mass flux enhancement and compared with previous studies using typical, non-partitioning, soluble electron donors such as lactate.

5.2 BASELINE CHARACTERIZATION

VOC impacts in the source zone (Hot Spot 1 Area) were delineated from 2008 to 2009 through a series of direct-push groundwater sampling events, a MIP investigation, saturated zone soil sampling and installation and sampling of a deep monitoring well (screen interval of 70 to 80 ft BLS). Sampling locations are shown in Figure 11. Figure 12 shows TCE concentration isopleths in Hot Spot 1 for the depth interval from 30 to 60 ft BLS. This figure presents dissolved-phase TCE concentrations from both direct-push groundwater grab samples and from permanent monitoring wells prior to the PED DEM/VAL. MIP results were used in conjunction with the concentration data to define the vertical interval of VOC-impacted groundwater, which was deemed to be the 30 to 60 ft BLS interval for the PED DEM/VAL.

Soil samples were collected in the Hot Spot 1 area during sonic drilling to install a deep monitoring well (IW0076, screen interval from 70 to 80 ft BLS) proximal to IW0002D and MIP0003 (refer to Figure 6). Continuous core was collected and logged to a depth of 80 ft BLS. Six discrete saturated zone soil samples (5 g each) were collected to assess TCE concentrations above, in and below the clay confining layer. The results were presented in the Technology Demonstration Plan (TDP); Lebrón and Major, 2011). The TCE mass distribution was consistent with the MIP logs and groundwater data, as shown in Figure 12.

Figure 12

I:\tbaylis\e2\1\DATA\GIS\5_TR\2010\2_ESTCP_LC34\MXD\LC34_Hot Spot_area 1_TCE_30_to_60ft.mxd 12 August 2010 MAH

This soil sampling was performed to evaluate the vertical concentration variations in the area, not to define the highest concentration of TCE at the site. Soil samples were intended to illustrate the depth interval where most of the TCE mass was located. The well was installed to confirm that the total depth of contamination was understood (and groundwater from the 70 to 80 ft BLS screen interval confirmed that VOCs were not present at that depth).

The CMS for the site (NASA, 2007) present theoretical soil concentrations for TCE-DNAPL saturation; a value of about 300 mg/kg is considered representative of NAPL-phase TCE. This value was determined using literature values for TCE solubility and organic carbon partition coefficient (K_{oc}), assumed values of bulk density and porosity, and measured values of the fraction of organic carbon (f_{oc}) for the site. The maximum TCE-DNAPL saturation value measured was 56.2 mg/kg^{dry}, which is equivalent to 42.7 mg/kg in the bulk soil. This would represent about 14% of the theoretical threshold value. On this basis the CMS concluded that DNAPL is likely present in the Hot Spot 1 area.

The groundwater concentrations are also indicative of a TCE-NAPL source: the source has been there for over 40 years and concentrations of TCE are still about 30,000 µg/L based on groundwater samples from the monitoring wells and DPT samples in the middle of the Hot Spot 1 area.

5.3 TREATABILITY OR LABORATORY STUDY RESULTS

A Laboratory Treatability Report (NAVFAC ESC et al., 2010) was prepared for the ESTCP review committee to present the results of the Laboratory Treatability Testing conducted as part of ESTCP project ER-0716. Laboratory treatability studies were conducted to evaluate candidate PEDs for eventual field application as part of the project. Based on prior research, consideration of physical-chemical properties, material costs, and toxicity, two candidate PEDs, nBA and nHEX, were selected for evaluation for enhanced microbial reductive dechlorination of TCE-NAPL.

The experiments conducted included:

(i) PED-NAPL Partitioning Studies to assess key physical-chemical parameters that are important for successful field implementation and included liquid-liquid equilibrium batch studies and mass transfer column experiments (abiotic columns);

(ii) Bench-Scale Treatability experiments to obtain site-specific design parameters for PED delivery, mass transfer, and enhanced microbial reductive dechlorination activity in a TCE-DNAPL source zone. These tests were designed to evaluate mass transfer of the partitioning electron donor and potential microbial activity under anticipated field conditions, and ultimately to demonstrate that the PED enhances reductive dechlorination activity and DNAPL dissolution rates.

Liquid-liquid equilibrium batch tests indicated that the partitioning behavior of both candidate PEDs (nHEX and nBA) could be characterized by ideal linear partitioning theory over the range of aqueous concentrations likely to be used in a field application (i.e. using initial dissolved-phase concentrations approaching aqueous solubility of the PED). Results demonstrated that based on partitioning coefficients nBA would partition more strongly into the NAPL than the nHEX. nBA was then selected for the field application. Abiotic column experiments further characterized the partitioning behavior of both candidate PEDs under flowing conditions in a well-characterized aquifer material (Federal Fine Ottawa sand). Tests were performed at a range of seepage velocities (1.2 to 6.0 meters per day [m/day]) in columns containing entrapped residual TCE-NAPL. Comparison of the column effluent breakthrough curves (BTCs) to predictions based on the one-dimensional advective-dispersive-reactive (ADR) transport equation indicated that PED partitioning occurred, but was not at equilibrium. The BTCs were fit with a 1-D ADR transport equation that incorporated a one-site solute non-equilibrium partitioning model. This model allowed calculation of a NAPL:water partitioning coefficient (K_{nw}), PED retardation factor (R_F) and a first-order mass transfer coefficient (k). The resulting data showed that nBA had a greater partitioning coefficient (and hence greater retardation factor) and slower mass-transfer rate than nHEX. The results confirmed the strong partitioning of nBA into TCE-NAPL. The results from these abiotic studies were published by Cápiro et al. (2011).

The strong partitioning of nBA into TCE- and surrogate-NAPL suggested that a single injection of PED solution was capable of providing electron donor to support microbial reductive dechlorination far beyond the number of PVs delivered, thereby reducing the need for frequent or repeated PED injections, independent of groundwater velocity. On this basis, nBA was selected as the PED for use in the bench scale biological treatability evaluation.

Microbial batch studies confirmed the efficacy of nBA as the electron donor to support the KB-1® Plus consortium to dechlorinate TCE and 1,1,1-trichloroethane (1,1,1-TCA). The results indicated that the KB-1® Plus consortium was able to degrade nBA and utilize it as an electron donor for dechlorination of TCE and 1,1,1-TCA. In these batch tests, the nBA-amended systems removed TCE and 1,1,1-TCA at dissolved concentrations of 5 mg/L over the same time period as the soluble methanol-ethanol-lactate (MEL) electron donor blend. Similarly positive results were obtained in systems containing surrogate NAPL and correspondingly high dissolved phase concentrations of TCE and 1,1,1-TCA (about 200 mg/L each). Results from the batch studies suggested that nBA would be a suitable PED for deployment in the field, based on the physical-chemical partitioning characteristics and the observed utility as an electron donor.

5.4 DESIGN AND LAYOUT OF TECHNOLOGY COMPONENTS

A primary objective of the project was to make the application of a PED similar to existing direct push injection approaches. The purpose of using a PED in place of a traditional electron donor was to maximize the bioremediation efficiency and improve the DNAPL dissolution rate, while minimizing implementation costs associated with the application of EISB in DNAPL source

zones. As such, the quantitative performance objectives established were to assess the PED application impact on primary parameters such as increased DNAPL dissolution (i.e. increased total VOC mass flux) and reduction in DNAPL mass. It was assumed that the application of PEDs would cost much the same as conventional donors on a per-application basis (for example, delivery using standard direct-push injection equipment from vendors), hence, if PEDs were effective longer (i.e., persisting longer results in less frequent donor amendment) and/or shorten remediation time frames, it would lower overall O&M costs. Therefore some components and tasks during the DEM/VAL were meant to assess the objectives and will not necessarily be required in future applications.

The system components included:

- extraction of groundwater from the center of the treatment area from extraction wells screened above and below the clay layer;
- injection of groundwater into injection wells screened above and below the clay layer surrounding treatment area;
- recirculation of site groundwater using a solar powered recirculation system;
- evaluation of mass flux without nBA enhancement by measuring VOC concentrations in samples from extraction wells (granular activated carbon [GAC] used to treat groundwater before reinjection during this phase) before nBA injection;
- injection of nBA using DPT into interval above and below the clay layer; and
- continued recirculation (no GAC treatment) and evaluation of mass flux and enhanced bioremediation using nBA by measuring VOC concentrations in samples from site monitoring wells and site soil samples.

For the field site the DEM/VAL was conducted in two zones, one above and one below the clay horizon. For this study these have been termed sweep zones as these are the areas where treatment is targeted. For each sweep zone, a groundwater recirculation system consisting of a central extraction well and five peripheral injection (recharge) wells was constructed to move groundwater through the PED-amended zone and maintain hydraulic control within the DEM/VAL area (Figure 13). The recirculation systems utilized solar-powered submersible pumps. The system components were housed in a mobile trailer, with the solar panels mounted to the roof. To supplement the existing monitoring wells, three multilevel monitoring well bundles were installed within the demonstration area at varying distances from the central extraction location. A schematic cross section of the DEM/VAL plot is provided in Figure 10, showing the locations of the well screens relative to the site lithology and the MIP data from the IW0076 location. Figure 14 shows the process flow diagram for the groundwater recirculation system.

Appendix B contains a summary of the well installation details. All borehole drilling and well installation was performed by a State-licensed driller, Environmental Drilling Services, Inc. (EDS), under the direction of a Geosyntec field geologist.

The groundwater recirculation system was installed in February 2011. It consisted of a mobile utility trailer that housed the system components and piping that carried the flow of groundwater from the extraction wells to the trailer and then to the injection wells. Parallel independent groundwater recirculation systems were operated for each of the upper and lower sweep zones. It should be noted that the recirculation system is not a requirement for application of the PED, but that for DEM/VAL it provided a controlled manner to assess performance. For each sweep zone, groundwater is pumped from the central extraction well and delivered to the five perimeter injection wells. A process and instrumentation diagram (P&ID) is presented on Figure 14. Appendix C contains a summary of the system operation details and supporting information.

The recirculation piping system was constructed using 0.75-inch diameter polyethylene (PE) tubing. The lines were run above-ground, enclosed in 2-inch diameter schedule 40 PVC for secondary containment. The upper and lower sweep zones had independent recirculation systems, with no mixing of fluid from one zone to the other. Submersible pressure transducers and data loggers were deployed in the extraction wells, six injection wells and two monitoring wells to measure and record water level fluctuations during system operation.

During the initial groundwater recirculation phase to establish baseline concentrations and mass flux, extracted groundwater was treated with GAC prior to re-injection. The GAC vessels were plumbed into the system so that extracted groundwater was treated before it entered the trailer and the flow was divided (see Figure 14).

The PED and conservative tracers (bromide and iodide) were amended throughout the DEM/VAL plot via a set of 20 DPT injection locations. This approach was selected to achieve better initial distribution of the PED throughout the target area, rather than amending recirculated groundwater. A licensed contractor with experience in DPT injection of bioremediation amendments was subcontracted to perform the injections. Equipment, specified and supplied by the contractor, included the following: DPT rod; injection tools (one capable of focused delivery to a 2-ft interval, one a 5-ft interval); pumps capable of supplying the required flow rates and injection pressures; manifolds with valves, pressure gauges and flow meters to measure and control the achieved flow rate and pressure at each location; and batch mix tanks, with requisite mixers and valves to ensure proper blending of the amendment fluids prior to injection. The instantaneous flow rate, injection pressure and the totalized flow rate were monitored and recorded during each injection event. The PED injection is discussed below (Section 5.5) and in Appendix C.

The target depth interval spanned an approximately 40 ft thick zone from about 23 to 63 ft BLS, encompassing the clay horizon within which TCE concentrations were elevated. The amendment zone included about 19 ft above the clay horizon, 6 ft within the clay, and about 15 ft

beneath the clay horizon. At each location, the injections were conducted in a series of steps, starting at the top of the target interval and working downwards. Injections mostly used a 2-ft injection tool to allow control of the delivery of amendment to targeted intervals; at a few locations a 5-ft injection tool was used.

The design involved injection of 34,000 gal of nBA solution (3,000 mg/L). This volume was selected to be approximately 50% of the total pore volume of the target zone. The amendment zone targeted the center of the Hot Spot 1 area, where TCE concentrations were greatest, roughly corresponding with the area enclosed by the 30,000 µg/L TCE isopleth and extending beyond that by approximately 5 ft in all directions (refer to Figure 12).

Two (2) conservative tracers were added to PED injection fluids. Bromide was used as a conservative tracer in all injection fluids, to provide an indicator of amended fluid; the concentration of bromide would indicate the proportion of injectate in any sample. Iodide was added as a tracer only in the injection fluids introduced above the confining silty clay horizon. The iodide was used to monitor for potential migration of fluid from the upper treatment zone through the clay to the lower zone, which could have occurred as a result of maintaining a lower hydraulic head in the lower zone.

Following PED injection, the recirculation system remained off for a period of six weeks to allow the PED to partition into NAPL within the demonstration area and to facilitate the acclimation and establishment of biomass within the demonstration area. Groundwater extraction during this 'shut-in' phase was undesirable, since it might have removed much of the amended nBA and re-injected it on the periphery. At the end of this Biomass Growth Phase, the distribution of PED and VOCs within the demonstration area was assessed through DPT soil sampling and a synoptic survey of groundwater concentrations.

After biomass growth phase was complete the groundwater recirculation system was activated. Recirculation of groundwater occurred for approximately thirteen months. During this time routine sample events took place to evaluate the effectiveness of the PED injection.

5.5 FIELD TESTING

The field DEM/VAL was implemented in accordance with the Demonstration Plan. Implementation of the experimental design consisted of seven main tasks as follows:

a. Installation and Shake Down (Task 1);
b. Baseline Soil and Groundwater Sampling (Task 2);
c. Baseline Flux Assessment (Task 3);
d. Introduction of PED and Tracers (Task 4);
e. Biomass Growth (Task 5);
f. Recirculation System Operation (Task 6); and
g. Demobilization (Task 7).

Table 2 presents a summary of the type and number of samples collected from each phase of the DEM/VAL. Figure 15 provides a Gantt chart of the technology demonstration schedule. Appendix C contains a summary of the operation of the groundwater extraction period. Table 3 presents a detailed summary of the O&M and sampling events. The following sections provide a brief summary of each operational phase of the DEM/VAL.

5.5.1 Task 1 – Well Installation and System Shake Down

A total of 30 wells (two central extraction wells, ten paired recharge wells and three multilevel bundle monitoring wells with six depth intervals each) were installed between 17 and 25 January 2011, as described in Appendix B, to complement the existing monitoring wells (four within the demonstration area and six located peripherally). The new wells were developed to remove fine sediments and ensure adequate hydraulic connection with the formation. Initial baseline groundwater samples were collected between 1 and 3 February 2011. Characterization of the well hydraulics was performed at select locations on 15 February 2011 using a pneumatic slug test technique. The system conveyance piping and infrastructure, including the trailer, solar system and extraction pumps, was then installed, connected and tested for leaks. The infrastructure for the PED DEM/VAL included a solar powered groundwater recirculation system mounted within a mobile trailer.

5.5.2 Task 2 – Baseline Soil and Groundwater Sampling

Baseline soil VOC concentrations were measured on soil samples collected on 19 January 2011 during installation of the extraction and multilevel bundle monitoring wells. Initial baseline groundwater samples were collected on 1 to 3 February 2011 from each of the newly installed wells and existing monitoring wells within the test area, and analyzed for VOCs to confirm the distribution of VOCs within the demonstration area. Details for this sampling event are provided in Appendix B and the results are provided in Appendix E and Section 5.7 below.

5.5.3 Task 3 – Baseline Flux Assessment

The groundwater extraction and recharge system was operated, without addition of PED, for a period of about 4 weeks to establish the baseline condition. Groundwater recirculation was initiated on 14 March 2011 and operated until 18 April 2011. During this time, samples were collected weekly from each central extraction well and up to six monitoring wells and analyzed for a variety of parameters as detailed above (refer to Table 3 and the sampling tables in Appendix D).

TABLE 2. TOTAL NUMBER AND TYPES OF SAMPLES COLLECTED

Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

STAGE	MATRIX	NUMBER OF SAMPLES	ANALYTE	SAMPLING FREQUENCY / LOCATION [1]
Stage 2 - Baseline and Stage 3 - Baseline Flux Assessment	Soil: Laboratory Measurement	19	VOCs (includes nBA)	4 locations within test plot, 4 to 6 depths per location
		8	Fraction of Organic Carbon	2 locations within test plot, 4 depths per location
		4	Grain Size Distribution	4 samples from location SB1002
	Groundwater: Field Measurement	na	Field Parameters (DO, ORP, pH, conductivity, temperature)	Data was recorded during all sample collection events
	Water: Laboratory Measurement	6	VOCs (includes nBA and n-butanol)	Effluent samples from GAC treatment
	Groundwater: Laboratory Measurement	94	VOCs (includes nBA and n-butanol)	Initial baseline from all wells including 6 perimeter wells and 4 injection wells; weekly from 2 RWs and 8 MWs for 3 weeks of recirculation; snapshot of all
		30	Volatile Fatty Acids	Weekly from 2 RWs for 3 weeks during recirculation; snapshot of all locations except perimeter wells at end of one month of recirculation
		30	Tracers (bromide & iodide)	Weekly from 2 RWs for 3 weeks during recirculation; snapshot of all locations except perimeter wells at end of one month of recirculation
		36	Total Organic Carbon	Weekly from 2 RWs for 3 weeks during recirculation; snapshot of all locations, including perimeter wells, at end of one month of recirculation
		26	Dissolved Hydrocarbon Gases	Biweekly samples from 2 RWs during recirculation (i.e. after about 2 weeks), and snapshot of all locations except perimeter wells at end of one month of recirculation
		15	Hydrogen Sulfide	Biweekly samples from 2 RWs during recirculation (i.e. after about 2 weeks), and snapshot of 2 RWs and 11 MWs at end of one month of recirculation
		15	Anions	Biweekly samples from 2 RWs during recirculation (i.e. after about 2 weeks), and snapshot of 2 RWs and 11 MWs at end of one month of recirculation
		15	Alkalinity	Biweekly samples from 2 RWs during recirculation (i.e. after about 2 weeks), and snapshot of 2 RWs and 11 MWs at end of one month of recirculation
		12	Dissolved Metals	Sampling at the end of one month of recirculation from 2 RWs and 11 MWs
		6	Microbial Characterization (*Dhc* 16S rRNA gene/*vcr* A)	Sampling at the end of one month of recirculation from 2 RWs and 4 MWs
Stage 4 PED Injection	Groundwater: Field Measurement	na	Field Parameters (DO, ORP, pH, conductivity, temperature)	Data was recorded during all sample collection events
	Water	17	VOCs (includes nBA and n-butanol)	Samples from selected batches of PED injection fluid
		17	Tracers (bromide & iodide)	Samples from selected batches of PED injection fluid
	Groundwater: Laboratory Measurement	29	VOCs (includes nBA and n-butanol)	Following PED injection, DP sample collection at 4 step-out locations, with 4 to 5 depths each; sampling at 11 select MWs
		25	Tracers (bromide & iodide)	Following PED injection, DP sample collection at 4 step-out locations, with 4 to 5 depths each; sampling at 11 select MWs
Stage 5 Biomass Growth	Soil: Laboratory Measurement	17	VOCs (includes nBA and n-butanol)	3 locations from test plot, 5 to 6 depths per location
	Groundwater: Field Measurement	na	Field Parameters (DO, ORP, pH, conductivity, temperature)	Data was recorded during all sample collection events
	Groundwater: Laboratory Measurement	24	VOCs (includes nBA and n-butanol)	Snapshot following shut-in period, all locations except perimeter wells
		24	Volatile Fatty Acids	Snapshot following shut-in period, all locations except perimeter wells
		24	Tracers (bromide & iodide)	Snapshot following shut-in period, all locations except perimeter wells
		24	Total Organic Carbon	Snapshot following shut-in period, all locations except perimeter wells
		24	Dissolved Hydrocarbon Gases	Snapshot following shut-in period, all locations except perimeter wells
		13	Hydrogen Sulfide	Snapshot following shut-in period, subset of locations (2 RWs, 11 MWs)
		13	Anions	Snapshot following shut-in period, subset of locations (2 RWs, 11 MWs)
		13	Alkalinity	Snapshot following shut-in period, subset of locations (2 RWs, 11 MWs)
		12	Dissolved Metals	Snapshot following shut-in period, subset of locations (2 RWs, 10 MWs)

TABLE 2. TOTAL NUMBER AND TYPES OF SAMPLES COLLECTED

STAGE	MATRIX	NUMBER OF SAMPLES	ANALYTE	SAMPLING FREQUENCY / LOCATION [1]
Stage 6 Recirculation System Operation	Soil: Laboratory Measurement	22	VOCs (includes nBA and n-butanol)	3 locations within test plot, 7 to 8 depths per location
	Groundwater: Field Measurement	na	Field Parameters (DO, ORP, pH, conductivity, temperature)	Data was recorded during all sample collection events
	Groundwater: Laboratory Measurement	84	VOCs (includes nBA and n-butanol)	2 RWs weekly for one month, biweekly for five months; snapshot at month 3 of all locations; snapshot at month 6 of all locations
		72	Volatile Fatty Acids	2 RWs weekly for one month, biweekly for five months; snapshot at month 3 and month 6 of all locations except perimeter wells
		72	Tracers (bromide & iodide)	2 RWs weekly for one month, biweekly for five months; snapshot at month 3 and month 6 of all locations except perimeter wells
		78	Total Organic Carbon	2 RWs weekly for one month, biweekly for five months; snapshot at month 3 of all locations except perimeter wells; snapshot at month 6 of all locations
		72	Dissolved Hydrocarbon Gases	2 RWs weekly for one month, biweekly for five months; snapshot at month 3 and month 6 of all locations except perimeter wells
		50	Hydrogen Sulfide	2 RWs weekly for one month, biweekly for five months; snapshot at month 3 and month 6 from subset of locations (2 RWs, 11 MWs)
		50	Anions	2 RWs weekly for one month, biweekly for five months; snapshot at month 3 and month 6 from subset of locations (2 RWs, 11 MWs)
		50	Alkalinity	2 RWs weekly for one month, biweekly for five months; snapshot at month 3 and month 6 from subset of locations (2 RWs, 11 MWs)
		48	Dissolved Metals	2 RWs weekly for one month, biweekly for five months; snapshot at month 6 from subset of locations (2 RWs, 10 MWs)
		12	Microbial Characterization (*Dhc* 16S rRNA gene/*vcr* A)	Snapshot at month 3 and month 6, from 2 RWs and 4 MWs
Stage 7 Interim Measure Recirculation System Operation	Soil: Laboratory Measurement	22	VOCs (includes nBA and n-butanol)	3 locations within test plot, 7 to 8 depths per location
	Groundwater: Field Measurement	na	Field Parameters (DO, ORP, pH, conductivity, temperature)	Data was recorded during all sample collection events
	Groundwater: Laboratory Measurement	64	VOCs (includes nBA and n-butanol)	2 RWs monthly for five months; snapshot at month 10 of all locations; snapshot at month 13 of all locations except perimeter wells
		48	Total Organic Carbon	Snapshot at month 10 and month 13 at all locations except perimeter wells
		48	Dissolved Hydrocarbon Gases	Snapshot at month 10 and month 13 at all locations except perimeter wells
		12	Microbial Characterization (*Dhc* 16S rRNA gene/*vcr* A)	Snapshot at month 10 and month 13, from 2 RWs and 4 MWs

Notes:

(1) There are 23 sampling locations (wells) within the treatment zone, including 2 RWs, 3 exisiting MWs, 3 nested multilevel MWs with 6 screen depth intevals each. There is 1 existing MW screened below the treatment zone. There are 3 far-field locations on the perimeter, each with a pair of wells screened above and below the clay horizon. Of the 10 injection wells, 4 were sampled at baseline. In addition, several DP locations were used for soil and groundwater sampling.

Dhc - *Dehalococcoides*
DO - Dissolved oxygen
DP - direct push
MW - monitoring well
na - not applicable
nBA - n-butyl acetate
ORP - oxidation reduction potential
RW - extraction well
vcr A - vinyl chloride reductase enzyme
VOC - volatile organic compound

TABLE 3. PED DEM/VAL EVENT SCHEDULE SUMMARY

Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Task Name	Date	Activity
Well Installation	17 to 21 and 24 & 25 January 2011	Well Installations & Baseline Soil Sampling
Baseline Sampling	1 to 3 February 2011	Baseline groundwater sampling
Baseline Sampling	15-Feb-11	Baseline hydraulic conductivity assessments
System Install & Shake Down	March 2011	Groundwater recirculation system constructed, including mobile trailer
	14-Mar-11	Groundwater recirculation system start up
Baseline Flux Assessment	22-Mar-11	BFA Week 1 Groundwater Sampling
	28-Mar-11	BFA Week 2 Groundwater Sampling
	7-Apr-11	BFA Week 3 Groundwater Sampling
	18 and 19 April	BFA Week 4 Groundwater Sampling Synoptic Survey
	18-Apr-11	Recirculation system shut down
Introduction of PED & Tracers	20 to 24 and 27 & 28 June 2011	PED Injection Activities
	30-Jun-11	DPT groundwater sampling (DPT328 – DPT331) to aid in evaluation of radius of influence from injection activities
	7-Jul-11	Groundwater sampling from select site monitoring wells; to evaluate nBA distribution
Biomass Growth Phase	July to August 2011	Biomass growth phase – recirculation system off
	1 to 3 August 2011	Post-biomass growth phase soil and groundwater sampling
Recirculation System Operation	9-Aug-11	Restart groundwater recirculation system
	12-Aug-11	Week 1 O&M and groundwater sampling (RW wells only)

At the end of this period of recirculation, on 18 and 19 April 2011, a comprehensive synoptic groundwater sampling event was conducted in which all monitoring locations were sampled to determine the baseline distribution of TCE and other parameters (refer to Table 3 and the sampling tables in Appendix D). The results from this synoptic is sampling for the baseline flux measurement phase served as the baseline event for post injection data analysis.

During this initial groundwater recirculation phase, extracted groundwater was treated with GAC to remove VOCs prior to re-injection.

5.5.4 Task 4 – Introduction of PED and Tracers

PED injection was performed from 20 to 28 June 2011 using an injection platform and DPT injection tools. Appendix C contains supplemental information on the PED and tracer injections. Fluid containing PED and tracers was amended throughout the demonstration area via a set of 20 DPT injection locations. A total of 34,000 gal (1,700 gal per injection point) of fluid containing 3,000 mg/L of nBA was injected, in a series of 2-ft intervals, into the target depth interval from 23 to 62 ft BLS.

Potassium bromide (KBr) was added to all injectate batches at a target bromide concentration of approximately 60 mg/L in the injection fluid. Relative bromide concentrations can be used to normalize PED concentrations to account for dilution. PED injection fluids for the upper zone were also amended with potassium iodide (KI) at a target iodide concentration of 140 mg/L in the injection fluid. This concentration was selected to be somewhat higher than for bromide, since it was expected that only relatively small amounts of fluid, if any, would be transported through the clay layer from the upper sweep zone to the lower sweep zone.

5.5.5 Task 5 – Biomass Growth Phase

Following PED injection, the recirculation system remained off for a period of six weeks to allow the PED to partition into NAPL within the demonstration area and to facilitate the acclimation and establishment of biomass within the demonstration area. Groundwater extraction during this ‘shut-in’ phase was undesirable, since it might have removed much of the amended nBA and re-injected it on the periphery. At the end of the Biomass Growth Phase, the distribution of PED and VOCs within the demonstration area was assessed through DPT soil sampling and a synoptic survey of groundwater concentrations. This would help to assess the partitioning effect of PED into residual DNAPL and establish a baseline before recirculation was restarted.

5.5.6 Task 6 – Recirculation System Operation

The groundwater recirculation system was activated on 09 August 2011 and operated for approximately thirteen months, until 13 September 2012. The first six months, through 16 February 2012, are considered the Main Recirculation Phase, which corresponds to the

duration of the DEM/VAL proposed in the TDP. System operation was continued for an additional seven months, through 13 September 2012, under an Interim Measure Work Plan (IMWP) for NASA. This continuation period is referred to as the Interim Measure Recirculation Phase (refer to Appendix C).

5.5.7 Task 7 - System Demobilization

The system was left to NASA at the end of the Main Recirculation Phase, to conduct the Interim Measure Recirculation Phase. At the end, the system was idled. NASA may decide to perform further remediation at Hot Spot 1 in the future partly utilizing some of the infrastructure in place.

5.5.8 Waste Disposal

Because the DEM/VAL system involved groundwater recirculation, only minimal waste was produced. All soils and liquids generated during drilling/coring, well purging and equipment cleaning were containerized by the drilling or sampling personnel in approved Department of Transportation (DoT) drums and placed on spill pallets provided by NASA. Investigation derived waste (IDW) characterization results were provided to NASA to facilitate proper disposal in accordance with applicable regulations and NASA standard site protocols.

5.6 SAMPLING METHODS

The sampling plan was designed to collect sufficient data to validate the performance of the PED technology under actual site conditions and allow potential end users to evaluate the technology. Table 2 summarizes the number and frequency of sample collection, types of samples, and analytes of interest. Table D-1 Appendix D provides details of the various groundwater sampling events. Table 4 presents the laboratory analytical methods used for the selected sample analyses. The soil and groundwater samples collected were analyzed for organic and inorganic parameters by methods specified in the USEPA's SW846 Methods, American Standard for Testing and Materials (ASTM) test methods, or laboratory-specific methods.

Sampling activities for the DEM/VAL, including field measurements, sample collection, decontamination, and documentation were performed in accordance with FDEP Standard Operating Procedures (SOPs) for Field Activities (DEP-SOP-001/01) dated March 31, 2008 (effective December 3, 2008) (FDEP, 2008) and the NASA Sampling and Analysis Plan (NASA, 2006). Appendix F contains a summary of the quality control and quality assurance metrics for the DEM/VAL.

TABLE 4. ANALYTICAL METHODS FOR SAMPLE ANALYSIS

Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Matrix	Analyte	Method[1]	Sample Container	Preservative	Holding Time
Soil	VOCs (includes nBA and n-butanol)	5035/8260C	4 oz. soil jars	Cool to 4ºC +/- 2ºC	14 days
	Fraction of Organic Carbon	Combustion [2]	4 oz. soil jars	Cool to 4ºC +/- 2ºC	28 days
	Total Organic Carbon	EPA LKahn 7-27-1988	4 oz. soil jars	Cool to 4ºC +/- 2ºC	28 days
	Grain Size Distribution	ASTM D 422 with hydrometer	Sealable plastic	None	None
	Microbial Characterization	Gene-Trac-Dhc (Method 1)[3] Gene-Trac-VC (Method 2)[3]	50 mL screw cap tube	Cool to 4ºC +/- 2ºC	10 days
Groundwater	Field Parameters (DO, ORP, pH, conductivity, temperature)	Field	NA	NA	NA
	VOCs (includes nBA and n-butanol)	8260C	3 x 40 mL VOA	cool to 4ºC +/- 2°C	7 days
	Dissolved Hydrocarbon Gases	RSK175	2 x 40 mL VOA	Cool to 4ºC +/- 2°C, preserved with HCl	14 days
	Volatile Fatty Acids	HPLC	250 mL HDPE	Cool to 4ºC +/- 2ºC	28 days
	Anions (chloride, nitrate, nitrite, sulfate)	300.0/353.2	125 mL HDPE	Cool to 4ºC +/- 2ºC	28 days (Nitrate/Nitrite 48 hours)
	Tracers (Bromide and Iodide)	300.0	125 mL HDPE	Cool to 4ºC +/- 2ºC	28 days
	Alkalinity	2320B	250 mL HDPE	No headspace, cool to 4ºC +/- 2ºC	14 days
	Dissolved Metals (arsenic, iron, manganese)	6010C	500 mL HPDE	field filtered prior to acid preservation with HNO_3 to pH <2, cool to 4ºC +/- 2°C	6 months
	Sulfide	SM 4500-S2- F	500 mL HPDE	Zinc Acetate and NaOH	7 days
	Total Organic Carbon	9060/9060A	250 mL plastic bottle	field filtered prior to acid preservation or filtered in lab within 48 hours of collection prior to acid preservation with H_2SO_4 to pH <2, cool to 4ºC +/- 2°C	28 days
	Microbial Characterization	Gene-Trac-Dhc (Method 1)[3] Gene-Trac-VC (Method 2)[3]	1 L HDPE	Cool to 4ºC +/- 2ºC	10 days

Notes:

1 - United States Environmental Protection Agency Method Number

2 - University laboratory method. Combustion in quartz tube furnace with infrared detection of carbon dioxide produced.

3 - SiREM Method (non-EPA). Genetic probe method using quantitative polymerase chain reaction (qPCR) analysis of the 16S rRNA gene (i.e., Gene-Trac-Dhc analysis) or the qPCR method used to quantify the Dehalococcoides vinyl chloride reductase (vcrA) gene (i.e., Gene-Trac-VC analysis).

ºC - degrees Celsius
Dhc - Dehalococcoides
DO - dissolved oxygen
H_2SO_4 - sulfuric acid
HCl - hydrochloric acid
HDPE - high density polyethylene
HNO_3 - nitric acid
L - liter
mL - milliliter
NA - not applicable
ORP - oxidation reduction potential
PED - Partitioning electron donor
SiREM - SiREM Laboratories, Guelph, Ontario
VOA - volatile organic analysis
VOC - volatile organic compounds

5.7 SAMPLING RESULTS AND ANALYSIS

This section presents the results obtained during the demonstration. Several Appendices contain supporting information specifically related to the results of the PED DEM/VAL, as follows:

- Appendix B – System Installation and Baseline Characterization
- Appendix C – Operations Summary
- Appendix D – Sampling Program Tables
- Appendix E – Data Summary
- Appendix F – Quality Assurance / Quality Control (QA/QC)
- Appendix G – Laboratory Analytical Reports

The results obtained from the PED evaluation are summarized in the subsections below.

5.7.1 Evaluation of Data Quality Indicators

During the DEM/VAL, data quality was assessed through evaluation of the data quality indicators (DQIs) precision, accuracy, representativeness, comparability, completeness, and sensitivity (PARCCS). Appendix F contains a summary of the QA/QC completed on the data. Evaluation of the PARCCS data quality indicators was completed to ensure that data quality objectives were met. Field QA/QC data did not indicate any major data quality issues. No analytes were detected in any of the trip blanks, field blanks, or equipment blanks, indicating there was no cross-contamination or introduction of contamination during sampling or sample transport. In the majority of instances the relative percent difference (RPD) between field duplicates and parent samples was acceptable.

Laboratory QA/QC data also did not indicate any major data quality issues. For the majority of cases, there were no detections in method blanks, hold times were met, and laboratory control sample/ laboratory control sample duplicate (LCS/LCSD) and matrix spike/ matrix spike duplicate (MS/MSD) recoveries and RPDs were within target ranges. In cases where laboratory QA/QC data were outside of data quality targets, the results are considered usable for the purposes of the study and the reported values represent estimated concentrations.

5.7.2 Baseline Characterization Activities

To characterize the baseline conditions, soil and groundwater samples were collected within the treatment zone. Soil samples were collected during well installation activities. Groundwater sampling included: a) an initial synoptic event (Task 2) to determine the initial VOC distribution within the demonstration area following well construction; b) routine sampling of the extraction wells and selected monitoring locations during recirculation to establish the baseline flux of VOCs (Baseline Flux Assessment Phase, Task 3); and c) a synoptic event to determine the VOC distribution at the end of the Baseline Flux Assessment Phase (Task 3). Appendix B contains a detailed summary of the data collection activities and Appendix E contains a summary of the

resulting data, including tabulated data from the baseline soil and groundwater sampling events. Table 2 summarizes the samples collected and Appendix D presents the groundwater sample collection program.

Operation of the recirculation systems during the Baseline Flux Assessment Phase is summarized in Appendix C. In the upper zone, 58.6 kilo gallons (kgal) were recirculated at an effective average flow rate (i.e. total volume divided by total time) of 1.16 gallons per minute (gpm), representing approximately 2.3 pore volume exchanges of the PED injection zone. In the lower zone, the cumulative volume of groundwater recirculated was 44.0 kgal, representing approximately 1.7 pore volume exchanges of the PED injection zone. The effective average flow rate for the system was 0.87 gpm.

Figure 16 shows the interpolated TCE distribution before PED addition, incorporating prior data and the results of baseline sampling. Figure 17 shows the soil sampling locations for the baseline event and all subsequent soil sampling events.

5.7.3 PED and Tracer Amendment

The PED injection was completed as planned. Fluid containing PED and tracers was amended throughout the demonstration area via a set of 20 DPT injection locations. Figure 18 shows the location of the twenty PED injection locations. A total of 34,000 gallons (1,700 gallons per injection point) of fluid containing 3,000 mg/L of nBA was injected into the target depth interval from 23 to 62 ft BLS. Injection rates typically ranged from 6 to 8 gpm, requiring pressures of 30 to 45 pounds per square inch (psi). Details of the PED and tracer injection, including individual records for each injection location, are provided in Appendix C.

A total of 115 gal of nBA, with a total mass of 380 kilograms (kg), was added to the DEM/VAL area. Batch QC samples confirmed that PED and tracers were mixed as intended and that the injection fluid contained the target compounds, with average concentrations of 3,000 mg/L of nBA, 72 mg/L of bromide and 107 mg/L of iodide (when added). The batch QC results are summarized in Table E1.3 in Appendix E.

Based on the target depth intervals, 50% of the total volume, or 17,000 gal of injectate, was amended to the upper sweep zone; 15% of the volume (5,100 gal) was amended within the silty clay horizon; and 35% of the volume (11,900 gal) was amended to the lower sweep zone. A total of roughly 11.6 kg of KBr was introduced to the treatment area, resulting in 3.9 kg of bromide to the upper sweep zone, 1.2 kg within the silty clay horizon and 2.7 kg to the lower sweep zone. A total of about 11.7 kg of KI (8.9 kg of iodide) was added to the 17,000 gal introduced into the upper zone.

Confirmation samples were collected to evaluate the effectiveness of the PED injections (refer to Appendix C). First, immediately following PED injections, DPT groundwater samples were collected adjacent to select PED injection points to assess the achieved radius of influence (see Appendix C and Table E-1-4 in Appendix E). The nBA concentrations were quite variable, both by location and depth, but this is often the case with direct push injections using conventional electron donor (e.g., with emulsified oils or lactate). The results suggested that the radius of influence was roughly 2 to 2.5 ft, consistent with the design estimates. The ratio of nBA to bromide was quite variable, suggesting that the nBA distribution may not be strongly correlated with the tracer, but the results generally showed that nBA was under-recovered relative to bromide, consistent with nBA partitioning and/or sorbing (see Table E-4-1 in Appendix E). Production of nBuOH was noted at a couple of locations, indicating that some hydrolysis had occurred within the first week (Table E-1-4).

Second, about a week after the PED injections were completed, groundwater samples were collected from a subset of the monitoring wells (see Appendix C for details). The results are presented in Appendix E. There was good distribution of nBA at these locations, with an average concentration of 400 mg/L. Also, at this point significant concentrations of nBuOH had been formed (up to 520 mg/L, with an average concentration of 184 mg/L), representing on average 38% of the PED in these samples. Table E-4-2 in Appendix E presents a comparison of the PED and tracer concentrations in these well samples. The ratio of normalized nBA concentration (considering nBA and nBuOH) to normalized bromide concentration was 0.77 on average. The normalized bromide concentrations suggested that the samples contained an average of 22% injectate, ranging from 3 to 62%. Where available, the iodide results were in agreement. The direct push injection approach that was suitable and distribution was sufficient to continue with the DEM/VAL.

5.7.4 Biomass Growth Phase

If the PED is a successful donor then a standard application would involve injection of the PED and then leaving this in place and treatment would be under ambient (i.e., unpumped) conditions. It was solely for the purposes of the DEM/VAL, to evaluate longevity and quantify effectiveness, that extraction of water was conducted. During this phase the majority of the PED occurred as nBuOH, indicating that the nBA had undergone considerable hydrolysis during this stage. Data indicates consumption of the PED due to microbial activity. The VOC concentrations in this phase indicate that considerable reductive dechlorination. This stage verified that PED injection with the direct push approach was able to provide additional donor and promote dechlorination.

As detailed in Appendix C, the recirculation system remained off for a period of six weeks following PED injection to allow the nBA to partition into NAPL within the demonstration area and to facilitate the acclimation and establishment of biomass within the demonstration plot. At the end of this period, the distribution of PED and VOCs within the demonstration area was assessed through DPT soil sampling and a synoptic survey of groundwater concentrations. These samples established the conditions prior to starting the recirculation system.

The groundwater results from this phase of the DEM/VAL are presented in detail in the various data tables in Appendix E. The nBA and nBuOH concentrations varied considerably throughout the demonstration areas, as did the TOC. The results show that the majority of the PED occurred as nBuOH, indicating that the nBA had undergone considerable hydrolysis during the shut-in period. On average, nBuOH was 84% of the total PED found (i.e. nBA plus nBuOH). The ratio of normalized total nBA concentration to normalized bromide concentration was 0.51 on average. The decrease in this ratio over the period of the shut-in period may reflect some additional partitioning and/or sorption of the PED, but it likely also reflects consumption of the PED due to microbial activity. The VOC concentrations from this event indicate that considerable reductive dechlorination had occurred. Figures 1 and 2 present the time trends for the extraction wells and show the VOC and VFA changes during the biomass growth phase.

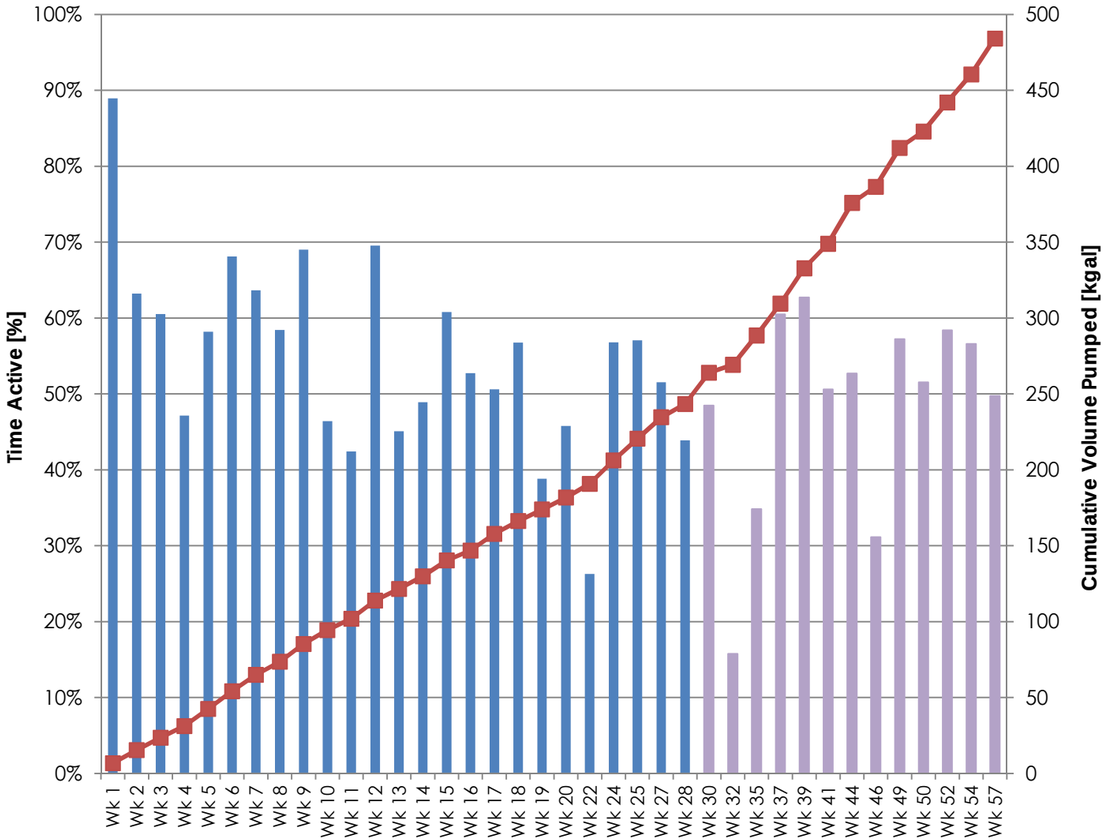
Soil samples were collected at the locations presented on Figure 17 to assess soil VOC concentrations. The VOC concentrations were highly variable with both location and depth, and overall the concentrations were greater than observed at baseline. This is attributable to natural spatial variation. Low concentrations of nBA and nBuOH were detected in some samples, but as there was no evidence in the samples collected of a NAPL phase, no correlation could be attempted.

5.7.5 Main Recirculation Phase

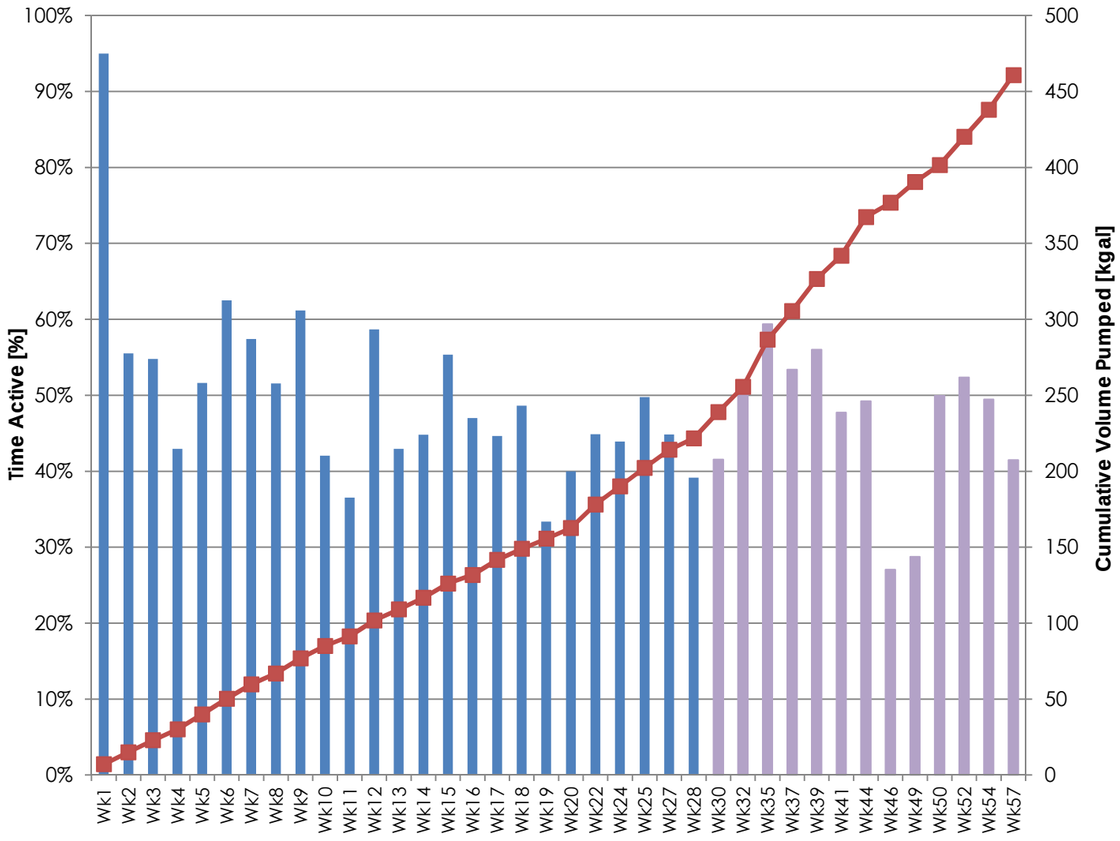
The Main Recirculation Phase occurred between 09 August 2011 and 16 February 2012. The recirculation systems generally operated as designed, although there were periods with no pumping due to limitations in the solar system. Details of the operations are reported in Appendix C, including volumes, flow rates, operating times and routine O&M information. No well rehabilitation was required. Appendix C includes hydrographs from select wells (the extraction wells, a pair of monitoring wells and a pair of injection wells). These clearly show the oscillation in water levels created by the groundwater recirculation system.

In the upper zone, 243.4 kgal were recirculated at an effective average flow rate (i.e. total volume divided by total time) of 0.89 gpm. With flow divided between five injections wells, the average effective injection rates were approximately 0.17 gpm per injection location. Overall, the system was active for about 53% of the time. Figure 19a presents the operating history for RW0007, showing the amount of time the system was active and the cumulative volume pumped over the duration of the DEM/VAL. Variations in the amount of time the system was active are apparent in Figure 19a; weather, and hence recharge of the solar-powered system was the main variable controlling system operation. It is estimated that the recirculated volume represents about 1.4 pore volumes of the sweep zone, or about 9.6 pore volume exchanges of the zone within which PED injection occurred (refer to Appendix C).

19a) RW0007



19b) RW0008



Notes:

1. Time Active represents the portion of the day in which the system operated. During this time, the pump cycled 40 minutes on, 20 minutes off.

2. The first 28 weeks (blue bars) represent the Main Recirculation System Operation Phase and subsequent weeks (purple bars) represent the Interim Measure Recirculation System Operation Phase.

3. Readings are not evenly distributed over time; less frequent recordings at later time create appearance of greater pumping rate (slope).

Operating History
RW0007 & RW0008
Launch Complex 34, Cape Canaveral, FL

Geosyntec consultants

Guelph | October 2013

Figure **19**

P:\PRJ\Projects\180272 - ESTCP_PED\04 ESTCP Reporting\21 Final Technical Report\03 FIGURES\[Figure 19b&b.xlsx]Fig 19b_b

Figure 19b summarizes the operating history for RW0008. A total of 221.6 kgal were recirculated in the lower zone at an effective average extraction flow rate of 0.81 gpm (average effective injection rates of approximately 0.16 gpm per injection location). The system was active for about 48% of the time, slightly less than in the upper zone (9% less). The recirculated volume represents about 1.7 sweep zone pore volumes, or about 8.8 pore volume exchanges of the PED injection zone (refer to Appendix C). These estimates of pore volume exchanges demonstrate that considerably more groundwater was recirculated than was initially amended with PED. This means the PED was sorbed and it stayed in place.

5.7.5.1 Groundwater Sampling - Main Recirculation Phase

Throughout the Main Recirculation Phase, groundwater samples were routinely collected to assess the VOC mass flux and evaluate the microbial reductive dechlorination of VOCs. Groundwater sampling is described in Appendix C and details of the sampling program are provided in Appendix D. The extraction wells were the main focus for routine sampling, with weekly sampling for the first month and then bi-weekly sampling thereafter. Synoptic surveys (snapshots) of the entire DEM/VAL plot, including extraction wells, bundle monitoring wells, existing site monitoring wells and the far-field monitoring wells (30 wells in total) was conducted at Month 3 (October 2011) and at Month 7 (February 2012). The types and numbers of samples are summarized in Table 2. The results are tabulated and presented in graphical form in Appendix E and discussed further below.

5.7.6 Interim Measure Recirculation Phase

Following the Main Recirculation Phase, the recirculation system was operated for an additional seven months, from 17 February 2012 through 13 September 2012, under an IMWP for NASA. Details of the operation are presented in Appendix C and summarized in Section 6. Figures 15 and 16 include the operating history for RW0007 and RW0008, respectively, during this Interim Measure Recirculation Phase.

System operation was essentially the same as during the prior phase; the average effective extraction rates at RW0007 and RW0008 were 0.82 gpm and 0.81 gpm, respectively (see Appendix C). Hydrographs for RW0007 and RW0008 for the period of operation are presented in Appendix C. The recirculated volume for the upper sweep zone was 240.9 kgal, representing an additional sweep zone 1.9 pore volumes, or approximately 9.5 additional exchanges of the PED injected area. In the lower sweep zone, the recirculated volume was 239.2 kgal, representing an additional 1.8 pore volumes, or approximately 9.5 additional exchanges of the PED injected area (see Appendix C).

5.7.6.1 Groundwater Sampling – Interim Measure Recirculation Phase

The groundwater sampling program was continued during the Interim Measure Recirculation Phase. Routine monthly samples were collected from the extraction wells, and synoptic surveys

were collected in Month 10 (June 2012) and at the end of operation in Month 13 (September 2012). Groundwater sampling is described in Appendix C and details of the sampling program are provided in Appendix D. The types and numbers of samples are summarized in Table 2. The results are tabulated and presented in graphical form in Appendix E and discussed further in the sections below.

5.7.7 Soil Sampling

Soil sampling activities are described in Appendix C. Soils samples were collected at the end of the Main Recirculation Phase (Month 7) and at the end of the Interim Measure Recirculation Phase (Month 13). The sampling locations, shown in Figure 17, corresponded to the locations sampled following the Biomass Growth Phase, to facilitate comparison over the course of the DEM/VAL. Table 2 presents the number of samples collected and soil VOC results are summarized and presented in Table E-1-1 in Appendix E.

Post PED injection, soil samples collected indicated PED was not present at the sampled locations. The PED, nBA, was only detected in a few locations, at very low concentrations. Minor amounts of nBuOH were observed in a couple of samples.

Similar results were obtained at the end of the Main Recirculation Phase (Month 7), with maximum TCE concentration of 75 mg/kg^{dry} at DPT0348. Again spatial variability appeared to be more significant than changes due to operation of the DEM/VAL. Similar results were obtained at the end of the Interim Measure Recirculation Phase (Month 13), with maximum TCE concentration of 75 mg/kg^{dry} at DPT0350. There was again considerable spatial variability.

Although it is admittedly a crude approach, all of the results for each event were averaged together to develop an average soil concentration (see table below) to estimate TCE and cDCE in soils at the locations sampled. There is some decline in the amount of TCE detected over the course of the DEM/VAL, from the end of the Biomass Growth Phase to the end of the Main Recirculation Phase (Month 7) to the end of the Interim Measure Recirculation Phase (Month 13). Note that baseline is quite different because it represents a different set of locations. However, the analysis is not very robust, given the observed degree of spatial variability.

Average Soil Concentrations (mg/kg)

	TCE	**cDCE**
Baseline	3.60	2.35
Post Biomass Growth	21.27	2.89
Post Main Recirculation Phase (Month 7)	13.07	5.83
Post Interim Measure Recirculation Phase (Month 13)	10.23	5.70

5.7.8 Groundwater Sampling Results

Groundwater samples collected from the central extraction wells (RW0007 and RW0008) make up the primary data set, which includes field parameters, VOCs, nBA, n-butanol, DHGs, VFAs, alkalinity, anions, dissolved metals, and microbial characterization numbers. Additional data was collected during synoptic events from the entire monitoring well network and used to support the interpretation.

Appendix E presents a summary of all of the analytical data collected for the DEM/VAL, including the extension referred to as the Interim Measure Recirculation Phase conducted for NASA's IMWP.

All of the data collected for the DEM/VAL is tabulated in Appendix E. There are several supporting attachments in Appendix E that contain the tabulated and graphed data collected during the DEM/VAL. A summary of key tables and figures is provided below.

Attachment E-1 contains summary tables for key groundwater parameters collected, including:

- Summary of PED Injectate Batch QC Sampling Results to verify the PED injected to the demonstration area (Table E-1-3)
- Summary of PED Injection Confirmation Grab Groundwater Sampling Results (Table E-1-4_
- Groundwater Sampling Results: Volatile Organic Compounds (Table E-1-5)
- Groundwater Sampling Results: Dissolved Hydrocarbon Gases, Anions & Tracers (Table E-1-6)
- Groundwater Sampling Results: TOC, VFAs and nBA (Table E-1-7_
- Groundwater Sampling Results: Dissolved Metals (Table E-1-8)
- Groundwater Sampling Results: Field Geochemical Parameters (Table E-1-9)
- Groundwater Sampling Results: *Dhc* and Vinyl Chloride Reductase (Table E-1-10)

Attachment E-2 presents time-series plots of selected analytes for each monitoring well location. For each monitoring location there is a set of four time-series plots, as follows:

A) VOC data using molar concentrations;
B) electron donor results, including nBA, nBuOH, VFA and TOC concentration data;
C) bromide and iodide tracer concentrations through the end of the Main Recirculation Phase (these analytes were not part of the sample program in the Interim Measure Recirculation Phase); and
D) geochemical parameters, including methane, ethane, sulfate and sulfide concentrations.

Attachment E-3 presents the VOC distribution history for each monitoring well location in the form of a stacked bar chart, which shows how the total VOC concentrations varied over time as

well as how the composition varied. These figures show the changes in total VOC concentration that were observed following PED addition.

Attachment E-4 provides a summary of the data analysis for assessing the impact of PED addition based on the conservative tracers amended during PED injection. A comparison of PED and tracer concentrations was conducted to confirm the experimental design was valid and to aid in confirming objective 3.6 (delivery of PED to source area). The tracer data collected and analyzed confirmed that PED was delivered to the source area and that it persisted for over 8 months of groundwater extraction/recirculation.

Attachment E-5 includes data analysis of the extraction wells to support the determination of the qualitative and quantitative objectives on PED effectiveness.

Attachment E-6 contains the supporting tables for the estimation of VOC and TVOC mass in the treatment zone over the operational period.

The following subsections present summaries of the key groundwater parameters.

5.7.8.1 VOC Trends

For the upper zone, VOC data from the central extraction well RW0007 (tabulated in Table E-1-5) is presented as a time-series in Figure 3a, including the Initial Baseline and Baseline Flux Assessment results. Figure 3b presents the time-series VOC data for the lower zone from the central extraction well RW0008. Other parameters (electron donors, tracers, and geochemical parameters) measured at the extraction wells are plotted in Appendix E (Attachment E-2). Figure 20 shows the VOC distribution history for RW0007 and RW0008, respectively. Appendix E similarly presents time-series plots (Attachment E-2) and VOC distribution plots (Attachment E-3) for the other monitoring locations.

For the upper zone, Figure 20a illustrates that the total VOC flux to RW0007 during the Main Recirculation Phase was less than during the Baseline Flux Assessment Phase, whereas the PED was anticipated to increase the TVOC flux. During Baseline Flux Assessment weekly samples were collected to assess VOC concentrations under pumping conditions. The TVOC concentration and the VOC distribution were stable in the baseline flux phase, with cDCE being the primary VOC. The presence of cDCE is attributed to the larger VOC plume associated with the source area beneath the ESB (refer to Section 4 above). TCE and CFC113 concentrations were also stable (Figure 3a). The concentration of TCE had decreased considerably by the end of the Biomass Growth Phase as a result of PED addition. Over the course of the Main Recirculation Phase, TCE and cDCE concentrations decreased while VC and Ethene concentrations increased, indicating that reductive dechlorination was active. This trend continued through the Interim Measure Recirculation Phase. It is noted that the continued presence of CFC113 may have limited reaction rates in the upper zone.

For the lower zone, Figure 20b illustrates that the total VOC flux to RW0008 during the Main Recirculation Phase was considerably greater than during the Baseline Flux Assessment Phase, indicating that PED addition increased the TVOC flux as anticipated. Note that the concentrations are considerably lower in the lower unit. During Baseline Flux Assessment weekly samples were collected to assess VOC concentrations under pumping conditions. The TVOC concentration and the VOC distribution were stable. TCE was the primary VOC and the cDCE concentration was about half that of TCE. The halo of the ESB plume was not observed in the lower zone at Hot Spot 1. During the Biomass Growth Phase there were strong indications of reductive dechlorination activity. The confirmation samples in July 2011 indicated a significant increase in the TVOC concentration, primarily attributed to cDCE and then the samples at the end of the shut-in period indicated that all of the VOCs at RW0008 had been converted to VC and ethene. Once recirculation was started, groundwater containing TCE and cDCE was drawn to the well. Over the course of the Main Recirculation Phase, TCE concentrations fluctuated somewhat but did not sustain a concentration below baseline until the Interim Measure Recirculation Phase. Concentrations of less-chlorinated products, cDCE, VC and Ethene increased over the operation of the DEM/VAL, indicating that reductive dechlorination was active. This trend continued through the Interim Measure Recirculation Phase.

The extent of reductive dechlorination was characterized by calculating the fraction of chlorine removed from the equivalent concentration of TCE, as described in Appendix E. The quantitative analysis of the extent of dechlorination is illustrated in Figure 4a for RW0007 and Figure 4b for RW0008, respectively. Note that complete conversion to DCE, VC, and ethene would correspond to dechlorination scores of 33%, 67% and 100%, respectively. These figures show that over the course of the DEM/VAL, both the upper and lower zones shifted increasingly toward complete dechlorination.

Figure 21 shows the estimated TVOC mass in the treatment zone based on the observed groundwater concentrations. The total mass of TCE, cDCE and VC is seen to decrease over the period of operation of the DEM/VAL.

5.7.8.2 Electron Donors - nBA and nBuOH, TOC and VFAs

The concentrations of nBA, nBuOH, VFAs and TOC are tabulated in Table E-1-6 and plotted in time-series figures in Attachment E-2 for each monitoring location. Donor concentrations observed at the central extraction wells, RW0007 and RW0008 in terms of the amount of carbon (i.e. mmol C/L) indicates the PED was a suitable electron donor and provided a sustained source of donor (refer to Tables E-5-5 and E-5-10 in Attachment E-5).

In water, nBA undergoes hydrolysis to form acetate and n-butanol. The n-butanol is utilized by fermenting organisms to produce butanoate, acetate, and hydrogen. Early time data, collected 9 days after completing the PED injection (PED injection occurred over a 9 day interval from 20 June 2011 to 28 June 201), indicated that, on average, n-butanol made up 38% of the total nBA equivalents detected in groundwater (the proportion of total nBA equivalents that was n-butanol ranged from 14% to 54%). After an additional 24 days (on 01 August 2011 & 02 August 2011), n-butanol comprised 84% of the total nBA equivalents detected. These data suggest that nBA underwent relatively rapid hydrolysis following its introduction to the DEM/VAL plots. Very little nBA was detected in groundwater samples collected from the extraction wells after the Biomass Growth phase; low concentrations were observed at the extraction wells during the Week 1 sampling (refer to Table E-1-5 in Appendix E), three days after groundwater recirculation was initiated, but not beyond that. At the Month 3 synoptic sampling, nBA was only observed at two of the bundle monitoring locations, BW0001B and BW0001D. nBuOH was present in extracted groundwater from RW0008 for only two weeks following system start-up and from RW0007 for four weeks. nBuOH was not detected in week 6, although low estimated concentrations of nBuOH were subsequently observed at RW0007 during weeks 8 through 12 suggesting that hydrolysis occurred.

Despite the relatively quick depletion of the nBA and nBuOH, the concentration of TOC did not decline as rapidly. TOC concentrations were sustained in both the upper and lower sweep zones, with the TOC concentration in the upper zone (RW0007) remaining above 100 mg/L though week 28 while in the lower zone (RW0008) remaining above 40 mg/L through week 28. After six more months of operation, TOC in the upper unit had decreased to 9.6 mg/L, or just above background levels, while in the lower unit the TOC declined to 27 mg/L.

VFAs accounted for most of the TOC, with acetate and butanoate being the most abundant VFAs identified in groundwater samples, along with minor amounts of propionate. When present, such as at early time, nBA and/or nBuOH contributed to the TOC. While acetate was a major component of the VFA, there was a significant contribution from butanoate, particularly in the upper zone. At RW0007, butanoate represented an average of 46% of the carbon occurring as VFAs over the initial 28 weeks of operation; the proportion was as high as 58% in week 4, declining to 27% by week 28. At RW0008, butanoate represented a smaller proportion of the VFA carbon, averaging 21% over the 28 weeks of recirculation, with a high of 47% in the first week declining to about 7% by the end of the DEM/VAL in week 28. Propionate made up 2 to 3% of the VFAs (as carbon) in both zones. The reason for the different relative composition of

the VFAs in the upper and lower zones is not known, but may reflect differences in the microbial populations responsible for fermentation of the various donor compounds. The difference may also reflect differences in the amount of nBA partitioned into NAPL and/or sorbed to the matrix; if more nBA was in fact sequestered in the upper zone, the higher proportion of butanoate observed here may have been the result of sustained release of nBA from residual NAPL and/or sorption sites.

The fact that nBA addition leads to the sustained supply of butanoate is a noteworthy feature of the technology. Soluble donors such as lactate and ethanol are more quickly consumed and TOC in these systems is quickly dominated by acetate. Also, butanoate has been shown to result in less methanogenesis than ethanol or lactate, because butanoate produces lower levels of hydrogen (Fennell et al., 1997).

5.7.8.3 Tracers

The tracer data is presented and analyzed in Appendix E. The concentration of bromide in extraction well RW0007 was always higher than that from RW0008, on average by a factor of about 3 (refer to Table E-1-6). The greater sustained concentrations at RW0007 suggest that more bromide mass was introduced to the upper sweep zone than the lower. No iodide was ever detected in monitoring locations in the lower zone, indicating that there was no significant movement of fluid from the upper sweep zone to the lower sweep zone. It was also noted that differences in the iodide and bromide recovery suggest that iodide may not have been conservative in the upper demonstration area.

Because PED was not detected in many samples after the first few weeks of operation, the bromide data was of limited utility to estimate partitioning. It did however serve as a tracer of the injection fluid and could be used to estimate the amount of blending that had occurred.

Average tracer concentrations at the end of the Main Recirculation Phase were used to estimate how much groundwater had been recirculated relative to the pore volume (refer to Appendix E). For the upper zone, this resulted in a rough estimate of 1.9 sweep zone pore volume replacements, which is in agreement with the estimate based on area and depth (refer to Appendix C). For the lower zone, this resulted in a rough estimate of 0.9 sweep zone pore volume replacements, which is somewhat lower that the estimate based on area and depth (refer to Appendix C).

5.7.8.1 Field Parameters

The field parameter data is summarized in Appendix E. The pH was generally about 7.5, varying somewhat spatially and temporally, but without apparent trends. Maintenance of neutral pH is conducive to promoting reductive dechlorination. The oxidation reduction potential (ORP) and dissolved oxygen (DO) concentrations indicated that suitable reducing conditions (ranging from sulfate reducing to methanogenic) were maintained throughout the DEM/VAL. Toward the

end of the Interim Measure Recirculation Phase, the ORP became less negative in the upper zone and DO concentrations increased slightly, to about 1.0 mg/L in both zones.

5.7.8.2 Geochemical Indicator Parameters

The geochemical indicator data, including DHG concentrations, is summarized in Appendix E. The methane and ethane data, as well as the sulfate and sulfide data for each monitoring location are plotted in the 'd' series of figures in Attachment E-2. Ethene is plotted with the chlorinated ethenes in the 'a' series of figures in Attachment E-2.

Production of ethene was observed in both the upper and lower zones, confirming that complete dechlorination of the parent VOCs (TCE, cDCE) through VC was occurring. Ethane was detected at many locations following PED addition. For example, at Month 3, the average ethane concentration in the upper zone was 25 µg/L, while in the lower zone it was 5 µg/L. Ethane is produced by the reduction of ethene, which is produced from dechlorination of TCE, cDCE and VC.

Methane was present in the groundwater from the beginning of the DEM/VAL, in the upper zone more so than the lower, with average baseline concentrations of 80 µg/L and 7 µg/L, respectively. Methane concentrations increased significantly over the course of system operation in both the upper and lower zones (refer to Appendix E). For example, at the Month 7 synoptic event, the average concentrations of methane were 290 µg/L and 330 µg/L in the upper and lower zones, respectively.

Sulfate concentrations were generally observed to decrease, while sulfide concentrations increased, indicating that the reducing conditions created by the addition of the PED stimulated indigenous sulfate reducing bacteria (refer to Appendix E).

5.7.8.3 Metals

Concentration data for dissolved Arsenic, Iron and Manganese over the course of the DEM/VAL are presented in Appendix E (Table E-1-8 in Attachment E-1). These species are known to be redox sensitive and are more mobile in their reduced forms. Dissolved Arsenic was not detected; dissolved Iron was observed initially at low levels; and dissolved Manganese was observed in most samples at low concentrations of 20 to 30 µg/L (below the FDEP GCTL of 50 µg/L). Manganese concentrations generally reached peak values at the end of the Biomass Growth Phase and then returned to background levels.

5.7.8.4 Molecular Characterization

The results of microbial characterization are presented in Appendix E (Table E-1-10 in Attachment E-1). Groundwater samples were analyzed to determine the presence and abundance of *Dhc* organisms, microbes that are capable of reductive dechlorination of chlorinated ethenes. Six locations were monitored over the course of the DEM/VAL, three in the upper sweep zone

(BW0001C, BW0003C and RW0007) and three in the lower sweep zone (BW0001E, BW0003E and RW0008). Baseline samples indicated that TCE-dechlorinating bacteria are native to the site; however, the number of *Dhc* organisms was relatively low. The Month 3 samples showed significant increases in *Dhc* organism numbers, with similar results over the course of the DEM/VAL indicating that the microbial population was sustained by the electron donors available with the plots.

In addition, the vinyl chloride reductase (*vcr*A) assay results confirmed that the native *Dhc* was capable of degrading VC to ethene efficiently. Data from the extraction wells indicated that initially the *vcr*A component made up only about 5% of the *Dhc*, but that over the course of operation the proportion of *Dhc* organisms that contained the *vcr*A component grew to be essentially 100%. This suggests that by Month 10 the entire *Dhc* microbial population had the capability of degrading vinyl chloride to ethene efficiently.

6 PERFORMANCE ASSESSMENT

6.1 EASE OF IMPLEMENTATION (QUALITATIVE)

To increase the likelihood that the PED technology will be adopted as an approach to source zone bioremediation, it should be straightforward to implement. Ease of implementation using standard equipment and application methods is an important benefit of the PED technology.

The ease of implementation was evaluated based on the experience of field staff and the actual availability and costs of installed equipment. The success criterion for this objective is that PED amendment to the source area is effectively achieved using readily available equipment.

This objective was achieved based on experience with the actual injection of nBA (the PED) at the Site. PED was successfully introduced to the source area using readily available direct-push injection equipment. The injection contractor performed essentially standard injections with a few extra precautions (e.g. bonding and grounding) for handling the pure nBA. Field application of nBA was deemed comparable to traditional soluble donor amendment in terms of equipment, time and effort, once the field crew were educated about nBA handling. The equipment required for the solar-powered recirculation system was also standard issue, readily available through local suppliers and assembled by technicians with training in basic plumbing techniques. Ease of implementation using standard equipment and application methods is an important benefit of the PED technology, since this facilitates it being adopted as an approach to source zone bioremediation.

6.2 ABILITY TO PROMOTE BIODEGRADATION (QUALITATIVE)

To be effective, the PED must have promoted biodegradation of the target contaminants. The reduction in contaminant mass is a function of the degree to which biodegradation was promoted in the subsurface. Due to budget constraints, a new control plot was not established for the DEM/VAL, but the project used the results from a prior pilot-scale demonstration at LC34 (Battelle, 2004; Hood et al., 2008) to compare PED efficiency to a soluble donor system (the previous study used ethanol). Addition of any electron donor can promote growth (biomass) which will in turn accelerate the consumption rate of donor (i.e., the donor consumption rate will vary in time and space) and as such it was not possible to statistically assess equivalent bioactivity between the prior study and the PED demonstration. Note that the goal was not to stimulate equivalent bioactivity – the prior LC34 demonstration experienced biofouling and maintenance to control biofouling was a significant cost. The goal was to demonstrate that the PED (nBA) could be utilized by the native dechlorinating microorganisms and had the ability to promote biodegradation of TCE.

The ability to promote biodegradation using the PED technology was evaluated on the basis of increases in the concentrations of dechlorination breakdown products and increases in the

population of microorganisms capable of dechlorination. Reductions in concentration of the parent compounds also contributed to the evaluation of biodegradation activity.

Groundwater samples were collected prior to donor amendment to establish baseline VOC concentrations and microbial numbers; groundwater samples were then collected over time during the demonstration to monitor changes in concentration and/or microbial numbers.

This objective was confirmed by the increases in the concentration of degradation products (cDCE, VC and ethene) from the reductive dechlorination of TCE and increases in the population of dechlorinating microorganisms in response to PED addition (Figure 4). In both the upper and lower demonstration areas, sustained production of dechlorination products, including ethene, was observed, demonstrating that the PED (nBA) could be utilized by the native dechlorinating microorganisms and thus had the ability to promote biodegradation of TCE.

6.3 LONGEVITY OF ELECTRON DONOR SUPPLY (QUALITATIVE)

Longevity of electron donor supply was assessed using the same time-series groundwater concentration data collected for assessment of several of the other objectives, namely the concentrations of remaining nBA, donor breakdown products (including n-BUT from nBA), VFAs, and TOC. Sustained donor supply from a one-time addition of PED is desirable, as it requires reduced frequency of donor replenishment.

This objective was confirmed by the persistence of electron donor equivalents throughout the DEM/VAL operation (see Section 5.7.8.2). The concentrations of nBA, nBuOH, VFAs and TOC are presented in Table E-1-7 and plotted in time-series figures in Appendix E for each monitoring location. Figures 22a and 22b show the VOC and donor trends for RW0007 and RW0008. Donor concentrations observed at the central extraction wells, RW0007 and RW0008 in terms of the amount of carbon (i.e. mmol C/L) indicates the PED was a suitable electron donor and provided a sustained source of donor (refer to Tables E-5-5 and E-5-10 in Appendix E). Measured TOC concentrations were generally equal to the sum of the individually quantified components. For example, at RW0007 the TOC concentration was, on average, 91% of the sum of the VFAs plus other carbon-containing compounds (nBA, nBuOH, VOCs and DHGs) and at RW0008, the TOC concentration was 99% of the sum of the VFAs and other measured carbon-containing compounds. TOC alone was monitored in the follow-on IM phase of operation, as it gave sufficient means to monitor the donor availability within the DEM/VAL plots.

The total TOC added to the system was 238 kg (from 384 kg of nBA). This equates to 119 kg to the upper zone, 37.5 kg to the silty clay zone and 83.3 kg to the lower zone. Figure E-4-3 in Appendix E shows the cumulative mass of TOC extracted from RW0007 and RW0008, respectively. These results were estimated by summing the product of the average TOC concentration and the volume of groundwater extracted between sampling events. The analysis was extended beyond the DEM/VAL, although TOC concentrations were only measured on two occasions, in weeks 47 and 58. Considering the results together, the cumulative mass of TOC

extracted was greater than the total mass of carbon in the nBA injected, which is an expected consequence of the recirculation of groundwater. When considering each separately, the mass of TOC extracted from the upper and lower zones exceeded the mass of nBA (as TOC) delivered to each zone respectively. This implies biomass grown in place may be enhancing the TOC.

6.4 PED PARTITIONS INTO THE DNAPL (QUALITATIVE)

The partitioning of PED into DNAPL was evaluated using groundwater analyses for conservative tracers (bromide and iodide), nBA and nBuOH, and TOC following PED injection. In the TDP (Lebrón and Major, 2011), it was suggested that nBA and VOC concentrations in soil would be analysed as well, but this was deemed impractical, as it would not be possible to determine whether the nBA and VOCs were in a NAPL phase or not. Because baseline soil data for VOCs showed considerable spatial variability and the presence of DNAPL was not confirmed, it was considered infeasible to attempt to quantify nBA within TCE-NAPL through soil sampling.

This performance objective was met. Although data collected in the field DEM/VAL did not have sufficient resolution to demonstrate PED partitioning into DNAPL the partitioning phenomenon was clearly demonstrated in the laboratory column experiments (Cápiro et al., 2011 and the laboratory summary report). The major reason for the apparent difference in behavior, between laboratory and field, is the amount of NAPL present in each case. As discussed in the TDP, the change in the aqueous concentrations of nBA should be proportional to the mass of residual NAPL present. In the laboratory column tests, the emplaced NAPL zone occupied 10-15% of the pore space. At this relatively high saturation, the NAPL phase can sequester a significant amount of nBA, resulting in a relatively large decrease in the aqueous phase concentration of nBA that can be readily detected. In contrast, the DEM/VAL field plots had low residual NAPL saturation (in fact, the degree of saturation could not be determined), such that only a relatively small amount of nBA would need to partition from the aqueous phase to establish equilibrium between the aqueous phase and any NAPL phase droplets. If only a small amount of nBA was sequestered from the aqueous phase, the resulting decrease in the concentration of nBA would be small and difficult to discern in the field data.

In the field, combined recovery of nBA and nBuOH shortly after PED injection (data collected 07-Jul-11 from 10 monitoring locations) was, on average, 93% of the bromide tracer recovery, suggesting some partitioning and/or sorption. Also, any additional breakdown products from the nBA were not accounted for, since TOC measurements were not collected at this time. Furthermore, there was considerable variation in relative recovery between monitoring locations, such that the standard deviation was 47%. Because of this, there is little confidence in the interpretation of the observed difference in terms of partitioned nBA. Later data is difficult to assess in this manner due to breakdown of the nBA, although the recovery of TOC relative to tracer gives some idea.

The 93% relative recovery is perhaps higher than might be expected once sorption of nBA to organic carbon in the aquifer is taken into account. Using the fraction of organic carbon determined on soils samples (Appendix E), a retardation factor of 1.4 was estimated for the upper sweep zone, suggesting that at equilibrium approximately 30% of the nBA might be expected to be sorbed to the matrix. When the aqueous nBA concentrations are scaled by a factor of 1.4 (with no scaling of the nBuOH since it is not expected to sorb strongly), the relative recovery of nBA and nBuOH is estimated to be 1.16 (±0.57).

6.5 PED Partitions out of the DNAPL at a Suitable Rate and Concentration (Qualitative)

The applied PED, once partitioned into residual DNAPL phases and onto sorption sites, must be released to groundwater at a rate and concentration that is sufficient to support bioremediation. The success of the technology relies on creating a sustained donor supply that matches the release of contaminants. The PED partitioning rate will be considered suitable if it occurs over the timeframe of the period of evaluation.

Assuming that PED partitioning into DNAPL is successful, the expectation is that PED will be released back to groundwater when dissolved-phase PED concentrations decrease as the un-amended groundwater is pulled into the treatment area due to removal from the central extraction wells. The intent is that this will sustain concentrations of nBA and/or its breakdown products that are greater than would persist in a soluble donor system after a pore volume of water has been extracted. In a soluble donor system, the donor will be removed with groundwater. In the PED system, donor is re-supplied from the DNAPL phase (and sorptive sites).

Assessment of this objective required use of nBA concentrations in groundwater over time, nBuOH concentrations, VFA and TOC concentrations, and VOC concentrations in groundwater. The assessment was not straightforward, as the nBA was actively consumed as it migrated toward the extraction well; however, evidence of sustained donor supply provided by the presence of dechlorination products should also support the evaluation. Changes in the amount of DNAPL dissolution were assessed by comparing the total flux of VOCs observed at the central extraction wells before and after application of the PED.

This performance objective was considered met. Sustained concentrations of electron donor (TOC and VFAs) were observed, with production of dechlorination products. Microbial numbers also increased. For the upper zone, the presence of elevated concentration of CFC-113 (which can inhibit dechlorination) and high initial concentrations of cDCE would mask the increase we wanted to observe. In the lower zone a sustained increase in total VOC mass flux was observed. Both upper and lower zones had near complete removal of TCE, only one location (BW0001D) had TCE remaining at the end of the DEM/VAL.

6.6 ABILITY TO DELIVER PED INTO THE SOURCE AREAS (QUANTITATIVE)

One objective of the PED DEM/VAL was to demonstrate that the PED can be readily delivered to the source area. In order to be an effective bioremediation approach, the application of PED should have been reasonably comparable to that of other traditional electron donors, so that its other properties can provide an overall benefit. The ability to deliver the design quantity of PED into the source area was expected to be comparable to that of other electron donors.

The objective was to be considered met if the design quantity of PED-amended fluid was delivered to the target zones within a reasonable amount of time (hours), using reasonable injection pressures. The success criterion was to amend at least 75% of the target volume (33,600 gal). This performance objective was met. The injection program successfully delivered the target volume and concentration of PED-amended fluid to the target zones: 34,000 gal of injectate containing 3,000 mg/L nBA with bromide and/or iodide as tracers was injected.

An additional consideration for this objective was that the post-injection concentrations of nBA, in soil and groundwater, would be well distributed following amendment. This objective was also met.

The ability to deliver the design quantities of PED to the target zones of the source area was assessed during installation, through observation of field implementation and monitoring of injection pressures and flow rates. Following amendment injection, the achieved distribution of PED was assessed through post-injection sampling of groundwater for tracers and nBA.

6.7 INCREASED DNAPL DISSOLUTION (QUANTITATIVE)

The PED technology is designed to provide electron donor at the NAPL:water interface to promote growth of dechlorinating biomass as close to the source of dissolved-phase VOCs as possible. By promoting and supporting reductive dechlorination close to the NAPL:water interface, the PED creates a steep concentration gradient between the NAPL and the aqueous phases, which results in increased DNAPL dissolution.

The amount of DNAPL dissolution was assessed by comparing the mass discharge of VOCs before and after application of the donor. Mass discharge is an integrated estimate of the mass flux, representing the total mass of any solute conveyed by groundwater through a plane, in this case a cylindrical surface around the extraction well. One advantage of this method is that the extraction well effectively integrates flow and concentration so that even small concentration hot spots and high-transmissivity zones are captured by the well and included in the estimate (ITRC, 2010). Typically this approach requires that the pumping well not increase the flow through the source zone, which might increase the dissolution rate (concentrations may or may not change), pumping be continued long enough that relatively steady-state conditions are achieved, and capture of the high-discharge portions of the plume must be complete or near-complete (ITRC, 2010).

The mass discharge was calculated from the groundwater VOC concentration data and the pumping rate and volume data. The total amount of TCE equivalents was calculated as the sum of TCE and its breakdown products, on a molar basis. The product of these measured concentrations and the volumetric pumping rate yielded an estimate of the total mass discharge rate. Using the pumped volumes, estimates of cumulative total mass discharge over time were determined. Changes in the total amount of TCE equivalents over time indicated changes in the rate of DNAPL dissolution. Interpretation was complicated by the fact that extracted groundwater was re-injected in the peripheral ring of injection wells without removing VOCs (or donor); dissolved species in groundwater removed from the extraction wells were re-introduced to the aquifer at the perimeter of the sweep zones. Estimates of the relative amount of recycle were obtained from comparison of the pumped volumes to estimates of the sweep zone pore volume, the tracer data and the TOC data.

It was expected that the PED plot would have increases in total VOC concentrations following amendment with nBA (relative to baseline). This increase in total VOC mass flux would be a primary indicator that the PED application worked as intended. The objective was to be considered met if the increase in total VOC mass flux observed in the PED plot was 50% or greater than that typically observed at sites where soluble donor was applied.

The result was partially confirmed. In the lower zone there was an increase in the total VOC mass flux to the extraction well. In the upper zone there was not an increase in total VOC mass flux to the extraction well. The lower zone enhancement factor was in the range for a typical donor application. DNAPL was not confirmed (i.e., observed) in the pilot test but the data collected indicate that there were additional TVOCs in the system.

Although the presence of DNAPL within the field plot was not confirmed the dissolved concentration data showed increases in the total amount of VOCs in some locations. Time trend plots of the VOCs at extraction wells RW0007 and RW0008 are presented in Figure 3. Appendix E contains time trend plots for the other monitoring well locations. The upper zone did not experience an increase in total VOC mass discharge at the extraction well, even though there was a definite shift towards lesser-chlorinated degradation products, as illustrated by the extent of dechlorination calculation shown in Figure 4. A number of factors may have contributed to this, including:

- Sustained elevated concentrations of cDCE;
- Sustained elevated concentrations of CFC113; and
- Distribution of TCE (and CFC113) – most of the mass was found at BW0001 upon installation and RW0007, suggesting there may have been DNAPL in that portion of the demonstration area, but not uniformly around the extraction well, so that the pumped groundwater represents a blend of water that passed through a source zone where contact with residual DNAPL was possible, and other water that came

from/through other portions of the demonstration area(s) where there was little TCE NAPL to contact.

The lower zone did experience an increase in total VOC mass discharge at the extraction well. The concentration trend is presented in Figure 20b. This figure shows that the increasing total VOC mass in extracted groundwater was due to increasing amounts of TCE degradation products.

The lower zone enhancement factor was in or above the range for a typical donor application. Data from RW0008 showed that, during the first three months, the ratio of TVOCs to the concentrations observed during the baseline recirculation phase was on average 2.4 times greater. The TVOC ratio increased to an average of 4.1 times over the next four months (i.e., months 4 through 7). Data collection during the subsequent Interim Measure Recirculation Phase was not as frequent, but at months 10 and 13, the TVOC ratio was 5.3 and 4.4, respectively.

6.8 IMPROVED EFFICIENCY OF ELECTRON DONOR UTILIZATION (QUANTITATIVE)

Because the PED will partition into residual DNAPL, and partition back into groundwater along with VOCs as they dissolve from the NAPL-phase, the electron donor may be preferentially utilized by dechlorinating bacteria. Hence, a greater proportion of the amended PED was expected to be used to support reductive dechlorination of VOCs rather than untargeted reactions (e.g., methane production).

The efficiency of electron donor utilization was assessed using the groundwater concentrations of VOCs, electron donors, breakdown products, and dissolved hydrocarbon gases (DHGs) over time. The parent donor compound, nBA, along with its breakdown products (n-butanol, acetate, and other VFAs), were monitored, in addition to the VOCs and their breakdown products, plus other compounds that may have formed, such as methane, so that a detailed understanding of the donor consumption pathways was ascertained.

The objective would be considered met if the ‘utilization ratio’ is greater for PED than is typically observed with traditional soluble donors. The success criterion will be an observed increase in utilization ratio of 50% or greater relative to the soluble donor system of the prior LC34 study (Battelle, 2004; Hood et al., 2008). That is, the units of TCE dechlorinated to units of ethanol applied for soluble donors will be compared to the units of TCE dechlorinated in the PED plot to units of PED applied).

The PED lasted longer than a soluble donor, several pore volume flushes were completed and if the donor was soluble it would have been extracted from the system. However, determining that the PED was more than 50% better than a soluble donor was not quantitatively determined. In the upper sweep zone significant cDCE was present at the start of the DEM/VAL and so production of cDCE from PED addition was not simply calculating the cDCE increase. This was not the case for the LC34 study. There were also elevated concentrations of CFC113 in many of

the collected groundwater samples which can inhibit dechlorination which would also limit confirmation of the objective. Nevertheless, the PED can be considered similar to other long term electron donors (e.g., emulsified vegetable oils) over the benefits of soluble donors (e.g., lactate or ethanol).

6.9 REDUCTION IN DNAPL MASS IN THE SOURCE AREA (QUANTITATIVE)

One goal of source zone bioremediation is to reduce the amount of DNAPL remaining in the source area, to reduce the expected time for clean-up. Reduced source mass may also result in reduced VOC loading to the downgradient plume.

Assessment of this objective was based on the baseline and final VOC concentrations in soil and groundwater. If the PED is able to partition effectively into residual DNAPL and this promotes bioactivity then a decrease in soil VOC concentrations should occur. This may increase groundwater VOC concentrations (in part due to production of daughter products).

The objective was confirmed based on the interpolated TVOC mass in the treatment zone. Figure 21 presents the interpolated TVOC mass accounting for sorption; there is a significant decline in TVOC mass, estimated to be a 77% reduction (Attachment E-6 in Appendix E). The sparse data set of soil samples, targeting specific locations, suggest there are some changes in TVOC but changes may not be sufficient to discern changes in TVOC mass across the entire treatment area.

6.10 REDUCE OPERATION AND MAINTENANCE COSTS (QUANTITATIVE)

A major feature of the PED technology is the reduced frequency of donor replenishment, the commensurate reduction in application costs, and the shorter remedial timeframes, resulting in lower operation and maintenance (O&M) costs, anticipated due to increased rates of DNAPL dissolution. The success of the PED technology depends on the degree to which these reductions in the number of applications and in the cost of operation and maintenance can be realized.

The reduction in operation and maintenance costs was estimated on the basis of the data collected during the DEM/VAL, including the costs for materials, labor and analytical costs. The time of operation relative to operation with a soluble donor was extrapolated using apparent DNAPL dissolution rates to estimate remedial timeframe. The observed longevity was used to estimate the frequency of re-amendment, to estimate costs over the lifetime of the remedy.

This performance objective was generally confirmed. The PED remained longer in the groundwater compared to a simple soluble donor (e.g., lactate) and promoted dechlorination. After 8 months of recirculation there was still enough residual organic carbon to promote bioactivitiy. On this basis we can conclude that the donor lasted longer than estimated, with no significant biofouling issues and hence less frequent donor addition and maintenance with the

PED over a soluble donor. Given this it would be likely that the PED will provide a shorter remedial timeframe but it is not exactly known if this will be a cost savings of 25% or more. However, the exact 25% reduction cannot be quantified, per se. At the end of the DEM/VAL VOC mass remained in parts of the test area and the time to completely treat remaining VOCs was not known.

7 COST ASSESSMENT

To assess and validate the expected costs of the PED technology, detailed cost information was tracked during the demonstration. This provides a cost summary for implementation of the technology and for comparing it to potential alternative technologies. An effort was made to identify and track cost elements unique to the PED technology so that the cost benefits of the PED technology could be assessed and realistic cost estimates could be made for implementation at a given site.

7.1 COST MODEL

The simplified cost model developed for the PED technology is presented in Table 5. The cost model reflects the elements that were incurred in the demonstration and that would be required to implement the technology for site remediation. In most cases, costs for the demonstration were greater than those anticipated for a typical application, due to extra efforts to collect sufficient data during the demonstration to validate the technology. Costs for implementing the technology at a selected site can be estimated using standard costs for the elements.

7.1.1 Cost Element: Laboratory Treatability Study

Although not absolutely required, a treatability bench scale evaluation would be conducted at most sites to determine the feasibility of implementing bioremediation at the site and to determine whether bioaugmentation was required. The cost listed in Table 5 represents the large-scope treatability testing conducted at Georgia Tech as a component of this DEM/VAL. This level of testing would not be necessary to assess a candidate site for implementation of the PED technology. Instead, a relatively straightforward evaluation of the applicability of bioremediation at a given site would be performed, costs for which should be included to properly compare the PED bioremediation technology to other source zone remediation technologies. Typical treatability study costs include the costs for collecting site soil and groundwater, setting up microcosms, and sampling and laboratory analysis.

7.1.2 Cost Element: Infrastructure Installation

The costs for infrastructure installation included the construction of the monitoring, injection and extraction wells plus the solar-powered groundwater recirculation system. These costs will be somewhat site-specific, as the numbers of wells and the costs to install them will depend on site characteristics (e.g., depth of wells, lithology, size of source area, etc.). A recirculation system, solar-powered or conventional, is not required, but proved useful for the DEM/VAL. In practice, the PED technology could be implemented in a range of scenarios from passive (i.e., no recirculation) to fully active (continuous recirculation, with or without routine PED addition).

TABLE 5. COST MODEL FOR APPLICATION OF PARTITIONING ELECTRON DONORS

Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Cost Element	Data Tracked During the Demonstration	Estimated Costs		
Laboratory Treatability Study	· Costs for collection of Site soil and groundwater	Total	$	100,000
	· Costs for treatability study in lab			
	· Materials			
	· Labor costs			
	· Laboratory analytical costs			
Infrastructure Installation	· Drilling (subcontractor)	Labor	$	33,534
	· Equipment costs	Expenses (including subcontractors)	$	57,080
	· Labor costs			
Baseline Sampling	· Laboratory analytical costs	Labor	$	4,742
	· DPT sampling (subcontractor)	Laboratory Analytical	$	5,175
	· Labor costs	Expenses (including subcontractors)	$	806
Installation and Amendment	· Direct push injection costs (subcontractor)	Labor	$	21,095
	· Material costs - Electron donor & Tracer	Electron Donor	$	3,065
	· Labor cost	Tracers	$	2,007
		Laboratory Analytical	$	6,484
		Expenses (including subcontractors)	$	59,810
Waste Disposal	· Investigation derived waste disposal costs	Expenses		NA
Operation and Maintenance	· Cost of labor for standard O&M	Labor		NA
	· Additional materials or labor costs for troubleshooting etc.	Expenses		NA
Performance Sampling	· Labor costs	Labor	$	50,713
	· Direct push soil sampling costs (subcontractor)	Laboratory Analytical	$	69,606
	· Laboratory Analytical Costs	Other Expenses	$	15,261
Regulatory/ Permitting	· UIC permit was obtained for NASA IMWP			
Total			**$**	**429,377**

7.1.3 Cost Element: Baseline Sampling

Baseline sampling costs included costs for collection and analysis of soil and groundwater samples. In practice these costs will be somewhat site specific since the number of samples and target analytes will vary. It should also be noted, that costs for baseline sampling would apply regardless of technology selected for a site's remedial approach.

7.1.4 Cost Element: Installation and Amendment

This element included costs for the materials (nBA and tracers), PED injection (injection contractor, oversight) and confirmation sampling (sample collection, analytical). These costs can be expected to vary between sites.

DPT injection was used to deliver the PED into the subsurface throughout each pilot test area. This method of amendment delivery involved the costs for an experienced injection subcontractor and for oversight labor during installation. This included costs for suitable equipment and safety gear to properly handle the nBA in its pure form (e.g., bonding, grounding). Other than that, there were no costs that were unique to the PED technology.

The overall cost for implementation of the PED technology will depend on the required number of re-applications. This is reflected in the cost analysis below.

7.1.5 Cost Element: Waste Disposal

This is a standard cost element; hence, it was not tracked during the DEM/VAL. Typical IDW disposal considerations will apply. In this case, NASA paid for disposal and the analytical costs for characterization were included with groundwater sample events.

7.1.6 Cost Element: Operation and Maintenance

No unique requirements were encountered. The costs for routine O&M during the DEM/VAL were not tracked separately, but are included in the Performance Sampling element (i.e., are included in Task 3 and Task 6 costs). Standard O&M costs can be used to estimate this element for full scale application of the technology.

7.1.7 Cost Element: Performance Sampling

Standard groundwater sampling and direct-push soil sample collection were used for monitoring the performance of the PED technology. The performance sampling costs were part of the demonstration assessment and were not typical for normal implementation of the PED technology. The costs for the detailed program were tracked and reported in Table 5, including labor, materials and laboratory analysis.

Some level of performance monitoring is required for any remedial technology. Since there are no unique sample collection or analytical requirements, the costs for a typical program can be estimated from standard monitoring costs for full scale application of the technology.

7.1.8 Cost Element: Regulatory / Permitting

The regulatory and permitting requirements are likely to vary from site to site, depending on the region and agency responsible for regulatory oversight. For the DEM/VAL, an underground injection control (UIC) permit was obtained by NASA for their IMWP. The PED, nBA, may have an MCL in groundwater as it does in Florida. Estimates of typical costs for preparation of permit requests and permit fees can be used to estimate the cost of this element for full scale application of the technology.

7.2 COST DRIVERS

The costs to implement the PED technology for DNAPL source zone treatment will vary from site to site, depending on the size of the site (i.e., impacted volume) and several site-specific characteristics. The key cost drivers are listed below along with a brief discussion of the impact on cost.

- Area to be treated – additional electron donor and direct push locations would be required
- Depth of source area
- Vertical thickness
- Naturally occurring groundwater quality – high concentrations of other electron receptors will increase the amount of donor required
- DNAPL Mass and Distribution

Also consider:

- Lithology & permeability – delivery in sands will be easier than in low permeability. Permeable (higher hydraulic conductivity) sites are likely to be better candidates for recirculation as a means of delivery and hydraulic control.

- Ambient groundwater velocity – site with higher velocity will have greater flushing of donor and potential influx of additional electron acceptors, both of which may affect PED utilization

7.3 COST ANALYSIS

A comparison is made between the PED technology and the most comparable in situ source zone treatment technology, conventional source zone bioremediation using non-partitioning electron donors. A cost analysis was conducted to calculate expected costs to treat a hypothetical site

with PED compared to using EVO, a widely accepted electron donor. The hypothetical site was assumed to have the following characteristics:

- Sand aquifer (30% porosity) that is 30 ft deep and underlain by a clay aquitard;
- DNAPL source zone is 40 ft wide by 80 ft long by 15 ft deep (15 to 30 ft bgs); and
- 500 kg of TCE DNAPL is present

Because PED is intended to be a source zone remedy, the cost comparison developed considers only treatment of the source zone and not the plume. For consistency, it is assumed that in both scenarios amendment of electron donor would occur via direct push injection at 40 injection points, each with a 5 ft radius of influence, evenly distributed across the source area. For both scenarios, the target injection volume is 50% of the source zone volume, which is considered a realistic value to sufficiently distribute the applied donor (PED or EVO). The assumptions for the cost analysis are summarized in Table 6. The mass of donor required, frequency of injection and total treatment time were varied in accordance with the known properties of each donor. Complete source zone treatment requires a substantial amount of time. The analysis compares the PED and EVO approaches for initial source zone treatment, after which the two scenarios converge since beyond the initial timeframe further remediation may still be required, but each scenario would likely need similar efforts to complete treatment.

Table 7 shows the total estimated treatment costs for the two scenarios – PED versus EVO. The calculated costs assume that the DNAPL and Site were previously well characterized. The total cost using PED as the electron donor was estimated to be $571,000, while the total cost using EVO was estimated to be $679,000. The differences in overall cost are attributable to the cost of donor applied in each event (which is a function of the unit cost and amount of donor required; the estimated number of applications is the same in both cases) and the duration of the remedy, which governs the number of monitoring events. Since other costs are likely to be similar between the two technologies, the cost savings with the PED technology arises primarily from the reduced duration of the remedy. The shorter duration is directly related to the enhanced DNAPL dissolution promoted by the PED.

The PED technology is applicable to the majority of sites with DNAPL source zones. Acceptance of the technology may significantly reduce remediation costs. The PED technology may also alleviate the drive to use other more aggressive and costly technologies to treat source zones, for example, thermal and chemical oxidation. Although the cost analysis presented here considered direct injection, groundwater recirculation systems could also be used. Existing pump and treat systems could benefit from introducing PED to create a small biological degradation/containment zone in and around the source area. This would eliminate or significantly reduce the amount of groundwater extraction (and associated costs) required to maintain containment while reducing the overall treatment time.

TABLE 6. ASSUMPTIONS MADE FOR THE BASIS OF THE COST ANALYSIS

Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

	PED		EVO	
	Value	**Rationale**	**Value**	**Rationale**
Assumed TCE Mass (kg)	500	Assuming 0.1% NAPL would give a TCE mass of 310 kg; Using the soil concentration of 300 mg/kg (which is NASA's concentration indicative of NAPL) gives a TCE mass of 650. Based on these a mass of 500 kg was selected/assumed.	500	Assuming 0.1% NAPL would give a TCE mass of 310 kg; Using the soil concentration of 300 mg/kg (which is NASA's concentration indicative of NAPL) gives a TCE mass of 650. Based on these a mass of 500 kg was selected/assumed.
Stoichiometric Donor Demand (kg)	83	Based only on TCE mass	64	Based only on TCE mass
Source Zone Volume (ft^3)	48,000	Assumes source zone is 40 ft wide, 80 ft long, and 15 ft thick.	48,000	Assumes source zone is 40 ft wide, 80 ft long, and 15 ft thick.
Depth of Aquifer (ft bgs)	30	Assumption	30	Assumption
Source Zone Pore Volume (ft^3)	14,400	Assumes porosity is 30%.	14,400	Assumes porosity is 30%.
Source Zone Pore Volume (L)	407,808		407,808	
Target Injection Volume (L)	203,904	Targets 50% of the pore volume.	203,904	Targets 50% of the pore volume.
Target Concentration of Injectate	3 g/L	Keep below nBA solubility (same as DEM/VAL)	1%	Typical oil concentration (from EVO) for source areas.
Target Mass of Donor into Formation (kg)	620		1,880	
Resulting Saftey Factor	7	(Target Mass into Formation)/ (Stoichiometric Donor Demand)	29	(Target Mass into Formation)/ (Stoichiometric Donor Demand)
Injection Points	40	Direct push on 10 ft centers (assume 5 ft radius)	40	Direct push on 10 ft centers (assume 5 ft radius)
NAPL Dissolution Enhancement	1.5	PED vs. EVO	1	
Treatment Time (years)	6.7	Assumed treatment will be 50% faster than EVO due to dissolution enhancement	10	Assumed 10 years of treatment
Treatment Frequency	Four Applications	Applied more frequently than EVO (every 2 years) because less TOC mass is applied in each application	Four Applications	Every 2.5 years
Total Donor Mass to Inject (kg)	2,500		7,600	

Notes:

1. Treatment applications are fixed to four for each technology. Treatment time is variable.

TABLE 7. COST COMPARISON OF PED TECHNOLOGY TO EISB USING CONVENTIONAL DONOR (EVO)

Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Notes:

1. Assuming basis parameters listed in Table 6.
2. Assumes semi-annual groundwater montitoring (for the assumed duration plus one year).

8 IMPLEMENTATION ISSUES

In the DEM/VAL it was confirmed that nBA can be a suitable option for source treatment. The nBA nBA was applied using conventional direct push equipment. No special equipment was required and injection used standard commercial off-the-shelf materials. It should be noted that the PED, n-butyl acetate, is a Class 1B flammable liquid. It is a colorless liquid that volatilizes to form dense vapors which have the potential to form an explosive mixture with air. Handling precautions such as bonding and grounding are required when working with the pure phase nBA. In addition, some plastics, such as those composed of polyvinyl chloride, are known to be attacked by nBA. Care must be taken to ensure that nBA is adequately dissolved if it is applied near PVC wells.

APPENDIX B

SYSTEM INSTALLATION AND BASELINE CHARACTERIZATION

APPENDIX B

SYSTEM INSTALLATION AND BASELINE CHARACTERIZATION

B.1 SYSTEM INSTALLATION

The DEM/VAL was conducted in two sweep zones, one above and one below the clay horizon. For each sweep zone, a groundwater recirculation system consisting of a central extraction well and five peripheral injection (recharge) wells was constructed to move groundwater through the PED-amended zone and maintain hydraulic control within the DEM/VAL area (Figure 13 of the main document). The recirculation systems utilized solar-powered submersible pumps. The system components were housed in a mobile trailer, with the solar panels mounted to the roof. To supplement the existing monitoring wells, three multilevel monitoring well bundles were installed within the demonstration area at varying distances from the central extraction location. A schematic cross section of the DEM/VAL plot is provided in Figure 10 (see main document), showing the locations of the well screens relative to the site lithology and the MIP data from the IW0076 location. Figure 14 (see main document) shows the process flow diagram for the groundwater recirculation system.

B.1.1 WELL CONSTRUCTION

Borehole drilling and well installation was performed by a State-licensed driller, Environmental Drilling Services, Inc. (EDS), under the direction of a Geosyntec field geologist. The field geologist maintained a complete record of the design and construction of each well and of all materials installed in the borehole (i.e., length of screen and casing, volume of sand and bentonite pellets, bags of cement, etc.). A total of 30 wells (two central extraction wells, ten paired recharge wells and three multilevel bundle monitoring wells with six depth intervals each) were installed between 17 and 25 January 2011. Table B-1 summarizes the well construction details. Well construction logs are provided as Attachment B-1 to this appendix. The lithology was assessed at the four soil boring locations (see below).

B.1.1.1 Extraction Well Installation

The two extraction wells (RW0007 and RW0008) were installed using hollow stem auger (HSA) techniques on 19 to 21 January 2011. Extraction well RW0007 was screened above the silty clay layer (35 to 42 ft BLS) and extraction well RW0008 was screened below the clay layer (47 to 57 ft BLS). The extraction wells were constructed of 6-inch diameter schedule 40 polyvinylchloride (PVC) risers and factory-slotted screens (0.020-inch slot size), completed in 14-inch diameter boreholes. The annular space around the well screen was filled with 6/20 sand filter pack followed by a 5-ft (minimum) thick bentonite seal. After allowing the bentonite chips to hydrate, the remaining annular space was grouted to surface with cement grout. The extraction wells were completed with an 18-inch x 18-inch steel well vault and 3-ft x 3-ft x

4-inch thick concrete pad. Two stub-outs, one for electrical wiring (1-inch diameter) and one for system piping (2-inch diameter) were installed in the wall of the vault box prior to completion. Construction details for the extraction wells are presented on Figure B-1. The well construction logs are included in Attachment B-1.

B.1.1.2 Injection Well Installation

Five injection well pairs (IJ0013 to IJ0022) were installed using HSA techniques on 17 to 20 January 2011. Each injection well pair consists of one injection well screened above the clay layer (32 to 42 ft BLS) and one injection well screened below the clay layer (47 to 57 ft BLS), completed in the same 10-inch diameter borehole. Injection wells were constructed of 2-inch diameter schedule 40 PVC with 0.020-inch slotted screen. The annular space around the well screens was filled with a 6/20 sand filter pack, extending 1-ft (minimum) above the screen interval, followed by a 2-ft (minimum) bentonite seal. Once the lower well was in place with its filter pack and bentonite seal, the upper well was installed in the borehole with its filter pack and seal. After allowing the bentonite chips to hydrate, the remaining annular space was grouted to surface with cement grout. The injection well pairs were completed at surface with an 18-inch x 18-inch steel well vault and 3-ft x 3-ft x 4-inch thick pad. Construction details of the injection wells are presented on Figure B-2. The well construction logs are included in Attachment B-1.

B.1.1.3 Bundle Monitoring Well Installation

Three bundle monitoring wells (BW0001A-F, BW0002A-F, and BW0003A-F) were installed using DPT on 20 to 24 January 2011. Each bundle well includes six individual monitoring wells with the following screen intervals: 23 to 26, 30 to 33, 37 to 40, 44 to 47, 51 to 54, and 58 to 61 ft BLS. The wells were constructed of ¾-inch schedule 40 PVC and screens with pre-packed filter packs consisting of 0.010-inch slotted screens surrounded with 20/30 filter sand. For wells A, B and C, 2 ft of 30/45 silica sand was placed as a seal above the pre-packed filter and the remainder of the hole was grouted to surface. For well D, a 2 ft bentonite sleeve was placed above the pre-packed filter and the remainder of the hole was grouted to surface. For wells E and F, two bentonite sleeves (4 ft total length) were placed 2.5 ft and 10 ft, respectively, above the pre-packed filter followed by grout to surface. The positions of the bentonite sleeves on wells E and F were selected to ensure a competent seal within the confining unit located at approximately 44 to 48 ft BLS. Annular space in between the pre-packed filter and the bentonite seal was allowed to fill with collapsed native material. Each bundle monitoring well was completed with a 4-ft x 6-ft x 4-inch thick concrete pad that contained the six individual monitoring wells (A through F), each with a separate 8-inch diameter steel cover. Construction details for the bundle wells are presented on Figure B-3. The well construction logs are included in Attachment B-1.

B.1.2 WELL DEVELOPMENT

Following installation, the newly installed wells were developed using standard surging and purging methods. The extraction wells were pumped with a centrifugal pump at rates up to 7 gallons per minute (gpm), with periodic stops to allow the well to recharge, until the turbidity had decreased and stabilized. A volume of 85 to 100 gal was removed from each extraction well. The injection wells were developed using a submersible pump, at rates of 1 to 2 gpm, to remove 20 to 30 gal from each until the water produced was clear of sediment. The bundle monitoring wells were developed with a peristaltic pump at an average rate of 0.15 gpm, removing approximately 5 gal from each. Development was continued until field parameters including turbidity had stabilized. Well development data for the bundle wells is included in Appendix C (Attachment C-2 Field Forms).

B.1.3 GROUNDWATER RECIRCULATION SYSTEM

The groundwater recirculation system was installed in March 2011. It consisted of a mobile utility trailer that housed the system components and piping that carried the flow of groundwater from the extraction wells to the trailer and then to the injection wells. Parallel independent groundwater recirculation systems were operated for each of the upper and lower sweep zones.

B.1.3.1 Solar Powered Recirculation System

The groundwater recirculation systems operated using solar power. For each sweep zone, groundwater is pumped from the central extraction well and delivered to the five perimeter injection wells. Groundwater was pumped from each extraction well using a 4.25-inch diameter submersible pump (Robison BL40Q). Each pump was powered by two 12 volt (V) deep-cycle marine batteries that are charged by two 85 Watt (W) solar panels (27-inch by 42-inch) mounted to the top of the 5-ft by 8-ft mobile utility trailer that houses all the recirculation system components. Other components housed in the trailer include charge controllers, timers, hour meters, sediment filters, sample ports, flow totalizers, a piping manifold, and individual flow meters for the ten injection wells. A process and instrumentation diagram (P&ID) is presented on Figure 14 (see main document).

When powered, the pumps provided a flow rate of approximately 2.5 gpm. Each pump circuit included a timer that was set to operate the system for 40 minutes of each hour. This timing cycle extended the effective time that the systems were active, in effect distributing the downtime throughout the day. This approach was selected because the solar panels could not always collect sufficient energy to fully recharge the batteries, resulting in periods of no pumping. The systems often experienced periods of complete shutdown overnight, depending on the weather. Occasionally a recirculation loop would be down for a longer period due to actual pump failures.

B.1.3.2 Recirculation System Piping

The recirculation piping system was constructed using 0.75-inch diameter polyethylene (PE) tubing. The lines were run above-ground, enclosed in 2-inch diameter schedule 40 PVC for secondary containment. The upper and lower sweep zones had independent recirculation systems, with no mixing of fluid from one zone to the other. The PE tubing was connected directly to the submersible pumps and exited the extraction vault boxes through the stub-out to run from the extraction well to the system trailer. Within the trailer, extracted groundwater passed through a filter assembly (20 micron), a totalizing flowmeter, and a flow-controlling globe valve before entering a distribution header. Each extraction line was equipped with a sample port to facilitate sample collection. Each of the two headers consisted of five parallel discharge lines, each equipped with a flow-control valve and rotameter allowing flow to be divided and balanced between the five injection wells in each sweep zone. The ten individual lines to the injection well pairs were similarly run within PVC for secondary containment, entering the injection vault boxes through the stub-out. Each injection line was extended into the injection well to act as a drop tube, so that returning groundwater was released approximately 2 feet below the static groundwater elevation.

B.1.3.3 Pressure Transducers

Submersible pressure transducers and data loggers (Solinst Leveloggers™) were deployed in the extraction wells (RW0007 and RW0008), six injection wells (IJ0013, IJ0014, IJ0017, IJ0018, IJ0019, and IJ0020) and two monitoring wells (IW0002D and IW0002D1) to measure and record water level fluctuations during system operation. The data loggers were programmed to record pressure readings every 15 minutes. The data loggers were deployed part way through the Baseline Flux Assessment phase, on 23 March 2011. After the Baseline Flux phase, the loggers were removed for PED Injection and re-deployed in eight locations (IJ0013, IJ0014, IJ0017, IJ0018, IW0002D, IW0002D1, RW0007 and RW0008) prior to initiation of the Main Recirculation Phase. The data was periodically downloaded during system maintenance visits. All data loggers were removed, except from the two extraction wells, on 05 April 2012 (week 35, except for the logger in IJ0013, which stopped at week 26). The data loggers in both extraction wells remained operational until the recirculation system was shut down on 11 September 2012.

B.1.3.4 Granular Activated Carbon

During the initial groundwater recirculation phase to establish baseline concentrations and mass flux (Task 3), extracted groundwater was treated with granular activated carbon (GAC) prior to re-injection. The GAC vessels were plumbed into the system so that extracted groundwater was treated before it entered the trailer and the flow was divided (Figure 14; see main document).

B.2 BASELINE CHARACTERIZATION

Baseline characterization involved collection of soil and groundwater samples within the test plot. Soil samples were collected during well installation activities. Groundwater sampling included an initial synoptic event (Task 2) to characterize VOC distributions within the test plot following well construction, and subsequent routine sampling of the extraction wells and selected monitoring locations during groundwater recirculation to establish the baseline flux of VOCs (Task 3). Task 3 included a synoptic event to determine the VOC distribution at the end of the Baseline Flux Assessment Phase. These activities are further described below.

Sampling activities, including field measurements, sample collection, decontamination, and documentation were performed in accordance with FDEP Standard Operating Procedures (SOPs) for Field Activities (DEP-SOP-001/01) dated March 31, 2008 (effective December 3, 2008) (FDEP, 2008) and the NASA Sampling and Analysis Plan (NASA, 2006).

B.2.1 SOIL SAMPLING

Prior to well installation, four soil cores (SB1001 through SB1004) were collected using direct push technology (DPT) techniques at locations corresponding to bundle wells BW0001, BW0002, and BW0003 and using hollow-stem auger with split spoons at extraction well RW0008 on 19 January 2011. The locations are shown in Figure 13 (see main report). At each soil boring location, to a depth of approximately 60 ft BLS, continuous-core soil samples were collected, examined and logged to confirm the local distribution of lithologic units and the depth and thickness of the silty clay horizon. Boring logs are provided with the field forms in Appendix C (Attachment C-2). The cores were screened in the field using a hand-held photoionization detector (PID) to assess where samples might be expected to contain high concentrations of VOCs and/or residual DNAPL. Nineteen subsamples (four to six samples from each location) were selected for laboratory analysis in the mobile lab (KB Labs) by EPA method 5035/8260. In addition, eight samples were collected for laboratory determination of the fraction of organic carbon (f_{oc}) and four samples for grain size distribution. Samples were also collected and archived for potential microbial characterization (*Dehalococcoides* [*Dhc*] and/or vinyl chloride reductase [*vcr*A] assay), although these samples were not analysed.

Results from the sampling event are compiled and presented in Table E-1-1 in Attachment E-1 in Appendix E. Laboratory results from this sampling event are provided in Appendix G.

Soil investigation derived waste (IDW) was contained in properly labeled 55-gallon drums which were stored on NASA provided spill pallets.

B.2.2 HYDRAULIC TESTING

Following well installation and development, on 15 February 2011, hydraulic testing of the extraction wells and four recharge wells was performed using a pneumatic slug test technique,

which used air pressure to disturb the static water level in the well while measuring and recording the response with a pressure transducer. The time-recovery data was then analyzed to assess the transmissivity of the formation at that well. The data was analyzed to obtain estimates of the hydraulic conductivity using the Hvorslev Method. Calculation sheets for these estimates are included in Attachment B-2.

B.2.3 GROUNDWATER SAMPLING

B.2.3.1 Initial Baseline

Baseline groundwater sampling was conducted to confirm VOC delineation and to establish pre-DEM/VAL conditions within, and in the vicinity of the Hot Spot 1 treatment zone. Baseline characterization comprised a synoptic survey (Task 2) of initial VOC concentrations following installation and development of the new wells in the test plots, followed by an assessment of VOC concentrations and distribution during groundwater extraction and recirculation (Task 3), including a second synoptic survey at the end of this baseline recirculation.

Two pre-exiting monitoring wells within Hot Spot 1 are screened above and below the target treatment zone; however, the upper monitoring well (IW0002S) could not be located and was believed to have been destroyed. Additional far-field perimeter monitoring well pairs are arranged in a triangular pattern around Hot Spot 1, located at distances of 160 ft to 240 ft from the center of the area (refer to Figure 13). These outlying monitoring well clusters provided monitoring locations to document that the PED DEM/VAL did not have a negative effect on surrounding groundwater conditions; these locations were included in the sampling program to demonstrate Underground Injection Control (UIC) permit compliance. The Groundwater Cleanup Target Level (GCTL) for n-butyl acetate is 43 µg/L.

The baseline synoptic survey of initial VOC concentrations (Task 2), conducted on 1 to 3 February 2011, included the collection of groundwater samples for field parameters, including depth to water, and VOCs from a total of 34 locations (refer to Table 2) comprising all bundle monitoring wells (BW0001A-F, BW0002A-F and BW0003A-F), four existing site monitoring wells (IW0002I, IW0002D, IW0002D1 and IW0076), four of the ten injection wells (IJ0015, IJ0016, IJ0019 and IJ0020), the two extraction wells (RW0007 and RW0008), and the six perimeter monitoring wells (IW0067D, IW0067D1, IW0070D, IW0070D1, IW0071D and IW0071D1). The sample collection table for the event is included in Appendix D and the samples collected are summarized in Table 2 of the main document.

Results from this Initial Baseline sampling event are compiled and presented in Tables E-1-5 (VOCs) and E-1-9 (Field Geochemical Parameters) in Attachment E-1 in Appendix E. The VOC data is included in Figures 3 and 4 for the extraction wells and the corresponding figures in Appendix E for other monitoring locations. The results were incorporated into the interpolated TCE distribution presented in Figure 16 (main document). The laboratory reports from this sampling event are provided in Appendix G.

B.2.3.2 Baseline Flux Assessment

Further characterization of baseline groundwater conditions was conducted during the Baseline Flux Assessment Phase (Task 3). This involved continuous groundwater extraction for a period of about 4 weeks, with routine weekly sampling of the extraction wells (RW0007 and RW0008) and select monitoring wells (BW0001C, BW0002C, BW0003C, IW0002I, and IW0002D in the upper zone; and BW0001E, BW0003E, and IW000D1 in the lower zone) to establish the baseline VOC profile and flux under pumping conditions in both the upper and lower sweep zones of the test plot. The Baseline Flux Assessment was conducted from 14 March 2011 through 18 April 2011. Groundwater samples were collected weekly for analysis for VOCs, nBA, and nBuOH. The samples from the extraction wells were also analyzed weekly for VFAs, tracers (bromide and iodide) and TOC, and biweekly for sulfide, DHGs, anions and alkalinity. The sampling program is provided in Appendix D. Details about the operation of the recirculation system during the Baseline Flux Assessment are provided in Appendix C.

At the end of this baseline flux assessment phase, a comprehensive synoptic groundwater sampling event was conducted. During this sampling event, the extraction wells, bundle monitoring wells and existing site monitoring wells (including the far-field monitoring wells surrounding the treatment area) were sampled (30 locations total) and analyzed for the following parameters (as listed in Table 2):

- Field parameters (DO, ORP, pH, specific conductivity, temperature, turbidity);
- VOCs (including nBA, nBuOH, TCE and related breakdown products);
- VFAs (including formate, acetate, lactate, propionate and butyrate);
- Tracers (bromide and iodide);
- TOC;
- DHGs (including methane, ethane, ethene);
- Anions (chloride, nitrate, nitrite, sulfate);
- Dissolved metals (iron, manganese and arsenic);
- Sulfide;
- Alkalinity; and
- Microbial characterization (*Dhc* and/or *vcr*A).

Details of the sampling program are provided in Appendix D and the samples collected are summarized in Table 2 of the main document.

Results from the Baseline Flux Assessment Phase sampling events are compiled and presented in Tables E-1-5 (VOCs), E-1-6 (DHGs, Anions and Tracers), E-1-7 (TOC, VFAs and nBA), E-1-8 (Dissolved Metals), E-1-9 (Field Geochemical Parameters) and E-1-10 (*Dhc* and *vcr*A) in

Attachment E-1 in Appendix E. The VOC data is plotted in Figures 1, 3, 4, and 20 and in the corresponding time-trend and VOC distribution plots included in Appendix E. The laboratory reports from these sampling events are provided in Appendix G.

B.2.3.2.1 GAC Treatment

During the Baseline Flux Assessment phase, extracted groundwater was treated with granular activated carbon (GAC) to remove VOCs so that no VOCs were re-injected on the perimeter of the test plots. Samples of the GAC effluent were collected periodically (weeks 2, 3 and 4), from sampling ports located inside the system trailer, to confirm the efficacy of treatment. The samples were analyzed for VOCs by EPA Method 8260C. The results, which are presented in Table B-2, confirmed that the GAC removed the VOCs.

B.2.4 INVESTIGATION-DERIVED WASTE (IDW)

Investigation-derived waste (IDW) collected during the installation activities consisted of soils and liquids generated during drilling/coring, well purging and equipment cleaning. All IDW was characterized and disposed of in accordance with NASA standard site protocols.

Soil IDW was collected in a 20-yard roll-off bin. A composite soil sample was then collected and analyzed for VOCs (EPA Method 8260C) and metals (EPA Method 6010C and 7471B), as well as leachable VOCs using the toxicity characteristic leaching procedure (TCLP; EPA Method 1311). Soil IDW (12.65 tons) was transported to the Omni Waste of Osceola County Landfill by Florida Environmental Compliance Corporation (FECC) for disposal as non-hazardous waste. Laboratory analytical results are provided in Appendix G and the non-hazardous waste manifest is included in Attachment B-3 to this appendix.

Liquid IDW was collected in properly labeled 55-gallon drums and stored on NASA-provided spill pallets secured with cargo straps. A liquid sample was collected from each drum and submitted for analysis for VOCs (EPA Method 8260C), the laboratory results were provided to NASA, and drums were disposed of by NASA.

Notes:

1. Northing and easting are referenced to the Florida State Plane Coordinate System, East Zone North American Datum of 1983.
2. Screen slot size is equal to 0.010 inches for all wells, except RW wells where slot size is 0.020 inches.
3. ft BLS indicates feet below land surface.
4. BW indicates bundle well.
5. DPT indicates direct push technology.
6. HSA indicates hollow stem auger.
7. INJ indicates injection well.
8. MW indicates monitoring well.
9. m indicates meters.
10. NS indicates not surveyed.
11. NA indicates not applicable.
12. RW indicates extraction (recovery) well.
13. UND indicates undetermined.
14. * indicates natural ground collapse.
15. ‡ Grey shading indicates well was lost and presumed destroyed.

Table B-2. Summary of Effluent from Granular Activated Carbon Treatment
Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Location	Sample Date	Trichloroethene (µg/L)	cis-1,2-Dichloroethene (µg/L)	trans-1,2-Dichloroethene (µg/L)	Vinyl Chloride (µg/L)	1,1,2-Trichlorotrifluoroethane (µg/L)
GAC Effluent	04/01/2011	0.3 U	0.3 U	0.3 U	0.3 U	0.61 I
	04/01/2011	0.3 U	0.3 U	0.3 U	0.3 U	0.4 U
	04/07/2011	0.3 U	0.3 U	0.3 U	0.3 U	0.6 I
	04/07/2011	0.3 U	0.3 U	0.3 U	0.3 U	0.4 U
	04/18/2011	0.3 U	0.3 U	0.3 U	0.3 U	0.4 U
	04/18/2011	0.3 U	0.3 U	0.3 U	0.3 U	0.4 U

Notes:

1. µg/L indicates micrograms per liter.
2. I indicates the result is between the method detection limit (MDL) and the practical quantitation limit.
3. U indicates result not detected above MDL.
4. Results not displayed to a set number of significant digits.

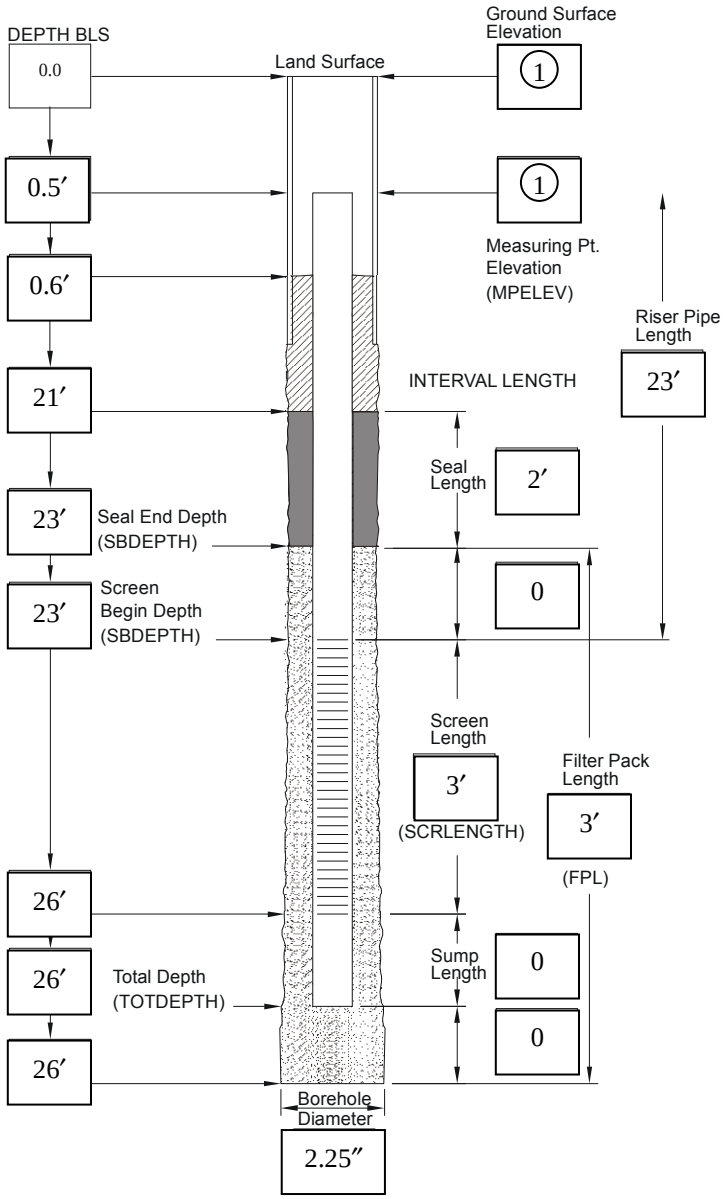
WELL CONSTRUCTION LOG
STANDARD FLUSH MOUNT

Well I.D.: LC34 – BW0001A

Drilling Company: EDS
Drillers: Chris Phelps, Keith Olson
Geologist/Engineer: Neil Stapley
Signature: For N.S.

Site: LC34
Project Number: TR0272
Installation Method: DPT
Casing Installation Date: 1/20/2011
Well Type: Monitoring Well
Well Completion Method: Flush Mount
Geologic Completion Zone: Surficial



Well Completion
Guard Posts (Y / (N)) Date: 1/25/2011
Surface Pad Size: 4 ft x 6 ft
Protective Casing or Cover
Diameter/Type: 8″ Steel Manhole
Depth BGS: - Weep Hole (Y / (N))
Grout
Composition/Proportions: ASTM C1157, Type GU Portland/Limestone Cement
Placement Method: Direct Pour

Seal Date: 1/20/2011
Type: 30/45 Silica Sand
Source: Standard Sand and Silica (~ ½ bag / 50 lb. bag)
Set-up/Hydration Time: 0 min.
Placement Method: Direct Pour
Vol. Fluid Added: ~ 5 gal.
Filter Pack
Type: 20/30 Silica Sand Pre-Pack
Source: Geoinsight
Amount Used: NA
Placement Method: Threaded PVC
Well Riser Pipe
Casing Material: SCH 40 PVC
Casing Inside Diameters: 3/4 in.
Screen
Material: SCH 40 PVC
Inside Diameter: 3/4 in.
Screen Slot Size: 0.010 in.
Percent Open Area: -
Sump or Bottom Cap ((Y) / N)
Type/Length: 0.2″ Bottom Plug (part of pre-pack)
Backfill Plug (Y / (N))
Material: -
Placement Method: -
Set-up/Hydration Time: -
Total Water Volume During Construction
Introduced (Gal): NA
Recovered (Gal): ~ 4

STANDARD FLUSH MOUNT

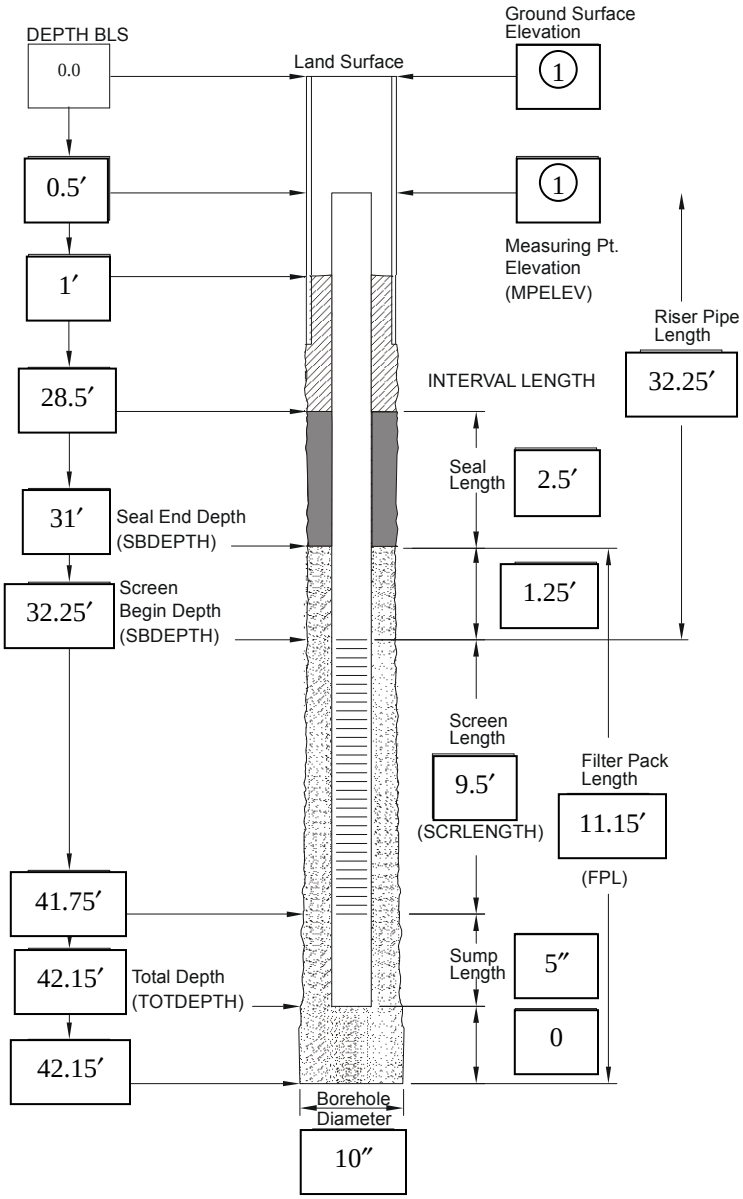
Well I.D.: LC34 – IJ0019

Drilling Company: EDS
Drillers: Mike Miller, Cory Cone, Carl Leonhardt
Geologist/Engineer: Rebecca Daprato
Signature:

Site: LC34
Project Number: TR0272
Installation Method: HSA
Casing Installation Date: 1/18/2011
Well Type: Injection Well
Well Completion Method: Flush Mount
Geologic Completion Zone: Surficial



Well Completion
Guard Posts (Y / (N)) Date: 1/24/2011
Surface Pad Size: 3 ft x 3 ft
Protective Casing or Cover
Diameter/Type: 18″ x 18″ x 10″ Vault Box
Depth BGS: - Weep Hole (Y / (N))
Grout
Composition/Proportions: ASTM C1157, Type GU Portland/Limestone Cement (~ 4 bags / ~ 20 gal.)
Placement Method: Tremie w/ pump

Seal Date: 1/18/2011
Type: Bentonite Chips (3/8″)
Source: Hole Plug (~ ½ bag / 50 lb. bag)
Set-up/Hydration Time: 15 min.
Placement Method: Direct Pour
Vol. Fluid Added: 0 gal., water added to casing for install
Filter Pack
Type: 6/20 Silica Sand
Source: Standard Sand and Silica
Amount Used: ~ 12 bags (50 lb. bag)
Placement Method: Direct Pour
Well Riser Pipe
Casing Material: SCH 40 PVC
Casing Inside Diameters: 2 in.
Screen
Material: SCH 40 PVC
Inside Diameter: 2 in.
Screen Slot Size: 0.020 in.
Percent Open Area: -
Sump or Bottom Cap ((Y) / N)
Type/Length: ~ 5 in.
Backfill Plug (Y / (N))
Material: -
Placement Method: -
Set-up/Hydration Time: -
Total Water Volume During Construction
Introduced (Gal): ~ 75 (for IJ0019 and IJ0020)
Recovered (Gal): ~ 30
Reviewed
By: Date: 1/31/11

Comments

HYDRAULIC CONDUCTIVITY TEST RESULTS

ATTACHMENT B-2
SUMMARY OF HYDRAULIC CONDUCTIVITY (K) BY HVORSLEV METHOD

INTERMEDIATE		
Well ID (screen interval, ft BLS)		K-Value (ft/d)
IJ0017 (32-42)	1	8.7
	2	9.1
	3	9.1
	4	10.3
IJ0021 (32-42)	1	3.5
	2	4.3
	3	4.2
RW0007 (34-41)	1	4.9
	2	4.8
	3	*
Average		6.6

DEEP		
Well ID (screen interval, ft BLS)		K-Value (ft/d)
IJ0018 (47-57)	1	4.2
	2	4.6
	3	4.1
IJ0022 (47-57)	1	5.5
	2	5.5
	3	3.7
RW0008 (47-57)	1	*
	2	3.8
	3	*
	4	4.4
Average		4.5

* Data was poorly correlated (not log-linear)

Notes

ft BLS - feet below land surface
ft/d - feet per day
K - hydraulic conductivity

Typical K Values

- clean gravel 1.0 to 10^{2} cm/s (2,800 to 280,000 ft/d)
- clean sands 10^{-3} to 1.0 cm/s (2.8 to 2,800 ft/d)
- very fine sands, organic and inorganic silts, mixtures of sand, silt and clay, glacial till, stratified clay deposits, etc 10^{-7} to 10^{-3} cm/s ($2.8x10^{-4}$ to 2.8 ft/d)

APPENDIX C

OPERATION SUMMARY

APPENDIX C

OPERATIONS SUMMARY

Table C-1 presents a summary of the operation and monitoring of the demonstration system from the beginning of well installation in January 2011 through the end of the completion of monitoring for the Interim Measure Recirculation in September 2012. The activities conducted during the various phases of the demonstration are described in the following subsections.

Appendix B summarized the system installation and baseline characterization activities.

C.1 TASK 3 – BASELINE FLUX ASSESSMENT

Baseline Flux Assessment was conducted from 14 March 2011 through 18 April 2011 to characterize baseline groundwater conditions. As described in Appendix B, this involved continuous groundwater extraction for a period of about 4 weeks, with routine weekly sampling of the extraction wells (RW0007 and RW0008) and select monitoring wells to establish the baseline VOC profile and flux under pumping conditions in both the upper and lower sweep zones of the DEM/VAL plot.

C.1.1 BASELINE FLUX ASSESSMENT – SYSTEM OPERATION

Details of the recirculation system operation, including the volume of groundwater recirculated and the effective average flow rate, are tabulated in Table C-2 for the upper zone (RW0007) and Table C-3 for the lower zone (RW0008). Note that the hour meters, which recorded when power to the pumps was on, were not added to the system until after the Baseline Flux Assessment Phase.

In the upper zone, the cumulative volume of groundwater recirculated was 58.6 kilogallons (kgal). The effective average flow rate (calculated from the volume and total elapsed time) for the system was 1.16 gpm. The system was active for about 75% of the time (active time includes the on/off cycle [40 min on/ 20 min off; refer to Appendix B]). The upper zone system (RW0007) generally operated longer, and in the fourth week of the Baseline Flux Assessment in particular; overall time of operation was about 39% greater than the lower zone (RW0008). The cumulative volume extracted from RW0007 over time is presented in Figure C-1 A. The volume of groundwater recirculated was estimated to represent roughly 0.5 sweep zone pore volumes or 2.3 pore volume exchanges of the PED injection zone (refer to Section C.4.1.1 below, and Attachment C-5 to this Appendix).

In the lower zone (RW0008), the cumulative volume of groundwater recirculated was 44.0 kgal. The effective average flow rate for the system was 0.87 gpm; the system was active for about 54% of the time. Time of operation and hence system flow rate slowed over the four week

period, as can be seen in the figure of cumulative volume extracted over time, presented in Figure C-2 A. This was attributed to the batteries poorly holding their charge. The volume of groundwater recirculated was estimated to represent roughly 0.3 pore volumes of the lower sweep zone or 1.7 pore volume exchanges of the PED injection zone (refer to Section C.4.1.1 below, and Attachment C-5 to this Appendix).

During the Baseline Flux Assessment phase, extracted groundwater was treated with granular activated carbon (GAC) to remove VOCs before re-injection. Routine monitoring of the GAC effluent confirmed treatment (see Appendix B); VOCs were not re-injected on the perimeter of the DEM/VAL plots during this phase. Upon completion, the GAC vessels were removed from the system and placed on NASA provided spill pallets, secured with a cargo strap and disposed of by NASA with related IDW.

At the end of the Baseline Flux Assessment Phase the groundwater recirculation system was idled, ready to be re-started following PED injection.

C.1.2 BASELINE FLUX ASSESSMENT – SYSTEM O&M

Weekly O&M activities for the four week duration of the Baseline Flux Assessment Phase included the following:

- inspection of wiring and piping;
- cleaning sediment filters, solar panels, and flow meters as needed;
- recording flow rates and volumes produced from extraction wells;
- rebalancing flow rates between injection wells;
- recording flow rates (initial and adjusted) to injection wells;
- recording battery voltage and charge status (percent charged); and
- correcting any operational abnormalities as needed.

C.1.3 BASELINE FLUX ASSESSMENT – GROUNDWATER SAMPLING

Samling during the Baseline Flux Assessment Phase was described in Appendix B. The sampling program is provided in Appendix D and the samples collected are summarized in Table 2 of the main document.

C.2 TASK 4 – INTRODUCTION OF PED AND TRACERS

C.2.1 PED INJECTION

PED injection was performed from 20 to 28 June 2011 using DPT injection tools. Vironex, a licensed contractor with experience in DPT injection of bioremediation amendments, was subcontracted to perform the injections. Fluid containing PED and conservative tracers (bromide and iodide) was amended throughout the DEM/VAL plot via a set of 20 DPT injection locations. This approach was selected to achieve better initial distribution of the PED throughout the target area, rather than amending recirculated groundwater. The amendment zone targeted the center of the Hot Spot 1 area, where TCE concentrations were greatest, roughly corresponding with the area enclosed by the 30,000 µg/L TCE isopleth and extending beyond that by approximately 5 ft in all directions (refer to Figures 16 and 18 in the main document).

The target area for PED injection was estimated to be approximately 750 ft^2. The area within the 300 µg/L TCE isopleth, which encompasses an area of about 4,000 ft^2, was chosen to define the sweep zone, with the injection well pairs placed at the periphery (Figures 12 and 16).

A total of 34,000 gallons (1,700 gallons per injection point) of fluid, representing approximately 50% of the total pore volume of the target zone, was injected into the target depth interval from about 23 to 63 ft BLS. The target depth interval encompassed the silty clay horizon within which TCE concentrations were elevated. The amendment zone included about 19 ft above the clay horizon, 6 ft within the clay, and about 15 ft beneath the clay horizon. At each location, the injections were conducted in a series of steps, starting at the top of the target interval and working downwards. Injections mostly used a 2-ft injection tool to allow control of the delivery of amendment to targeted intervals; at a few locations a 5-ft injection tool was used. To the extent practicable, injections began at the periphery of the treatment area and proceeded inwards; the injection locations were completed in numerical order (refer to Figure 18), at first two and then three locations at a time (refer to the Vironex Injection Services Report in Attachment C-1 of this Appendix). Based on the target depth intervals, 50% of the total volume, or 17,000 gal of injectate, was amended to the upper sweep zone; 15% of the volume (5,100 gal) was amended within the silty clay horizon; and 35% of the volume (11,900 gal) was amended to the lower sweep zone.

The PED injection fluid was prepared in small batches in two 250-gal plastic tanks, alternating between them so that one batch could be injected while another batch was blended. Each batch contained a concentration of approximately 3,000 mg/L of nBA (roughly half of its solubility). Amendment batches were mixed for 15 minutes prior to injection to ensure complete dissolution of the nBA and tracer salts. A total of 115 gal of nBA, with a total mass of 380 kg, was added to the DEM/VAL area.

Injection rates typically ranged from 6 to 8 gpm, requiring pressures of 30 to 45 pounds per square inch (psi). At the bottom of each injection location, 10 to 35 gal of water was used to flush the lines. When injection at a location was complete, the injection tool was removed, standard DPT rods were pushed to depth and the borehole was tremie grouted to surface with Portland cement. During all injection activities, a photoionization detector (PID) was used to screen the air in the work area to ensure that a safe working environment was maintained. A summary of the injections, including individual records for each injection location, is included in the Injection Services Report (Attachment C-1). Field forms from the injection activities are provided in Attachment C-2.

C.2.2 TRACER INJECTION

Potassium bromide (KBr) was added to all injectate batches at a target bromide concentration of approximately 60 mg/L in the injection fluid. A total of roughly 11.6 kg of KBr (containing 7.8 kg of Br) was thus introduced to the treatment area. Relative bromide concentrations can be used to normalize PED concentrations to account for dilution. Based on the distribution of injectate volume between zones, 3.9 kg of bromide was added to the upper sweep zone, 1.2 kg within the silty clay horizon and 2.7 kg to the lower sweep zone.

PED injection fluids for the upper zone were also amended with potassium iodide (KI) at a target iodide concentration of 140 mg/L in the injection fluid. A total of about 11.7 kg of KI (containing 8.9 kg of I) was added to the 17,000 gal introduced into the upper zone. This concentration was selected to be somewhat higher than for bromide, since it was expected that only relatively small amounts of fluid, if any, would be transported through the clay layer from the upper sweep zone to the lower sweep zone.

C.2.3 PED AMENDMENT BATCH QUALITY CONTROL

A total of 155 batches of nBA injection fluid, each about 220 gal in volume, were prepared over the course of the injection program. To verify the actual concentrations of nBA and tracer obtained, quality control (QC) samples were collected from a random selection of the batches and submitted for laboratory analysis for nBA and tracer anions (bromide and iodide). Batch QC samples were obtained from a sample port in the injection manifold. Each day, 2 or 3 batches were sampled, resulting in a total of 17 batch samples representing roughly 10% of the total (refer to Table 2 of main document).

Results from the batch QC sampling are compiled and presented in Table E-1-3 in Appendix E. The laboratory reports are provided in Appendix G.

C.2.4 PED INJECTION CONFIRMATION SAMPLING

Two types of confirmation samples were collected to evaluate the effectiveness of the PED injections. Immediately following PED injection, DPT groundwater samples were collected at several depths adjacent to select PED injection locations to assess the radius of influence (ROI) achieved. A week later, groundwater samples were collected from select monitoring well locations within the DEM/VAL plots.

C.2.4.1 PED Injection DPT Groundwater Sampling

On 30 June 2011, two days after completion of the PED injection activities, DPT groundwater samples were collected at the four locations (DPT0328, DPT0329, DPT0330, and DPT0331) presented on Figure C-7 and analyzed in a mobile laboratory for nBA and VOCs. Split samples were submitted to a fixed laboratory for analysis of bromide and iodide. A subset of the split samples were also analyzed in the fixed laboratory for VOCs including nBA and nBuOH. A total of 18 samples were collected, from 4 or 5 depths per location.

The locations were sampled in order, starting at DPT0328. The positions were adjusted in the field in response to the results obtained by the mobile lab. Locations DPT0330 and DPT0328 were located about 2 feet and 4 feet from the nearest injection location (IP09), respectively. These locations evaluated nBA distribution at a single injection location on the periphery.

The other two sample locations evaluated nBA distribution closer to the interior of the injection grid, where more than one injection occurred. Location DPT0329 was located about 2.5 feet from the nearest injection location (IP16), and location DPT0331 was located about 6.0 feet from IP16, but within about 3.5 feet of IP06.

Sample locations were tremie grouted to surface following sample collection.

The results (VOCs, nBA, nBuOH and tracers) from the confirmation DPT groundwater sampling are compiled and presented in Table E-1-4 in Attachment E-1 in Appendix E and an analysis of this data is presented in Table E-4-1 in Attachment E-4 in Appendix E. The laboratory reports (from both the mobile and fixed laboratories) are provided in Appendix G.

C.2.4.2 PED Injection Monitoring Well Groundwater Sampling

To further assess the distribution of PED following injection, on 07 July 2011, nine days following the end of the injection event, samples were collected from eleven monitoring wells (BW0001C/D/E, BW0002C/D/E, BW0003C/D/E, RW0007, and RW0008) and laboratory analyzed for VOCs, nBA and nBuOH, and tracers (refer to Table 2 and Appendix D). During well purging, field parameters, including pH, temperature, dissolved oxygen (DO), oxidation-reduction potential (ORP), conductivity, total dissolved solids (TDS), and turbidity, were recorded at regular intervals until consecutive readings had stabilized.

The results from this confirmation sampling event are presented in Tables E-1-5 (VOCs, nBA and nBuOH), E-1-6 (Tracers) and E-1-9 (Field Geochemical Parameters) in Attachment E-1 in Appendix E; this data is also presented in Table E-4-2 in Attachment E-4 in Appendix E. The results are plotted in Figures 1, 3, 4, and 20 of the main document for the extraction wells (and the corresponding figures in Appendix E for other wells). The laboratory reports are provided in Appendix G.

C.3 TASK 5 – BIOMASS GROWTH PHASE

Following PED injection, the recirculation system remained off for a period of six weeks to allow the PED to partition into NAPL within the DEM/VAL plot and to facilitate the acclimation and establishment of biomass within the DEM/VAL plot. Groundwater extraction during this 'shut-in' phase was undesirable, since it might have removed much of the amended nBA and re-injected it on the periphery. At the end of the Biomass Growth Phase, the distribution of PED and VOCs within the DEM/VAL plot was assessed through DPT soil sampling and a synoptic survey of groundwater concentrations. This was intended to help to assess the partitioning effect of PED into residual DNAPL and establish a baseline before recirculation was restarted.

C.3.1 BIOMASS GROWTH PHASE – GROUNDWATER SAMPLING

Twenty-four locations, including the extraction wells, bundle monitoring wells and monitoring wells, were sampled on 1 and 2 August 2011. The samples were laboratory analyzed for VOCs, nBA and nBuOH, VFAs, tracers (Br and I), TOC, Sulfide, DHGs, Anions, Alkalinity, Dissolved Metals and microbial characterization (archived). The analyses are summarized in Table 2 and detailed in Appendix D.

Results from the Biomass Growth Phase sampling event are compiled and presented in Tables E-1-5 (VOCs, nBA and nBuOH), E-1-6 (DHGs, Anions and Tracers), E-1-7 (TOC, VFAs and nBA), E-1-8 (Dissolved Metals) and E-1-9 (Field Geochemical Parameters) in Attachment E-1 in Appendix E. The VOC data is plotted in Figures 1, 3, 4 and 20 of the main document and in the corresponding time-trend and VOC distribution plots included in Appendix E. The TOC and VFA data is also plotted in Figure 2. The VOC data is used in the plume mass estimates in Section E.6.1 and Attachment E-6 in Appendix E and Figure 21 of the main document. Attachment E-5 in Appendix E presents the organic carbon data (VOCs, nBA, nBuOH and VFAs) on a molar basis. The laboratory reports from these sampling events are provided in Appendix G.

C.3.2 BIOMASS GROWTH PHASE – SOIL SAMPLING

On 3 August 2011, three soil cores (DPT0332, DPT0333, and DPT0334) were collected using DPT techniques at the locations presented on Figure 17 (main document). Seventeen sample intervals were selected by PID screening. Subsamples were collected and analyzed for VOCs

and nBA. In addition, the cores were visually logged to document soil lithology. Boring logs are provided with the field forms in Attachment C-2 of this Appendix. Soil IDW was contained in properly labeled 55-gallon drums which were stored on NASA provided spill pallets secured with cargo straps.

Results from the soil sampling event are presented in Table E-1-1 in Attachment E-1 in Appendix E. Laboratory results from this sampling event are provided in Appendix G.

C.4 TASK 6 –RECIRCULATION SYSTEM OPERATION

The groundwater recirculation system was activated on 09 August 2011 and operated for approximately thirteen months, until 13 September 2012. The first seven months (28 weeks), through 16 February 2012, are considered the Main Recirculation Phase, which corresponds to the duration of the DEM/VAL proposed in the TDP. System operation was continued for an additional seven months, through 13 September 2012, under an Interim Measure Work Plan (IMWP) for NASA. This continuation period is referred to as the Interim Measure Recirculation Phase.

C.4.1 RECIRCULATION SYSTEM OPERATION - SYSTEM OPERATION

C.4.1.1 Main Recirculation Phase

Details of the recirculation system operation, including the volume of groundwater extracted and re-injected, the time of operation, the effective average flow rate and the percentage of time active, are tabulated in Table C-2 for the upper zone (RW0007) and Table C-3 for the lower zone (RW0008).

Figure C-5 presents the hydrograph of the water level in the upper extraction well (RW0007) for the first month of operation. The effect of the 40 minutes on, 20 minutes off timing cycle is clearly shown in the oscillation of the water level. The response to pumping is rapid (on and off). The shape of the curve is partly due to the recording frequency of 15 minutes; data is recorded at varying points in the drawdown/recovery cycle. The figure also shows the longer shut off periods, when the system ran out of power, typically a little after midnight. Peak drawdown was about 7.5 feet, with an average drawdown of about 4 feet, estimated as the midpoint of the oscillating water level during active pumping. Hydrographs for the remainder of the recirculation system operation are presented in Attachment C-4 to this Appendix.

Figure C-6 presents the hydrograph of the water level in the lower extraction well (RW0008) for the first month of operation. Hydrographs for the remainder of the recirculation system operation are presented in Attachment C-4 to this Appendix. A similar pattern in the water level was observed in RW0008, with fine oscillations resulting from the timing cycle and larger overnight idle periods. In RW0008 the peak drawdown was approximately 27.5 feet, with

average drawdown of approximately 22 feet. At RW0008, the water level did not fully recover during the 20 minute downtime in the pump cycle; recovery was about 15 feet. Hence, during the period of active cycling, an effective hydraulic gradient was maintained towards the well. Greater drawdown reflects a lower transmissivity at RW0008, since the pumps operated similarly at about 2.5 gpm when powered. The difference in drawdown between the extraction wells meant that there was generally a hydraulic gradient downward across the silty clay confining layer in the vicinity of the extraction wells.

Attachment C-4 includes hydrographs for wells IW0002D, IW0002D1, IJ0013 and IJ0014 during the Main Recirculation Phase (after which the leveloggers were removed and were not deployed during the Interim Measure Recirculation Phase). The influence of the extraction wells is shown in the hydrographs for wells IW0002D and IW0002D1, which are located 6.7 feet and 11.9 feet from RW0007 and RW0008, respectively. For example, during Week 3 (last week of August 2011), drawdown at IW0002D was about 0.46 ft and at IW002D1 was about 0.60 ft. Response to pumping was immediate, and the fine oscillations of the timing cycle were observed in both the upper and lower zones.

In both the upper and lower zones, the flow of extracted water was split evenly between five peripheral injection wells (Figure 13 in the main document). The flow splits were checked and rebalanced during the routine O&M visits (see Section C.4.2 below). Flow to each injection well was approximately 0.5 gpm during actual pumping. The effective average injection rates were approximately 0.17 gpm per injection location in the upper zone (0.16 gpm in the lower). Hydrographs for a pair of injection wells, IJ0013 and IJ0014, are presented in Attachment C-4. For IJ0013 the mound during pumping was approximately 1.7 ft (perhaps half this, 0.85 ft on average during active cycle). For IJ0014, the injection mound during pumping was approximately 2.4 ft. Comparison of the hydrographs suggests that an upward hydraulic gradient may exist both during active pumping and during non-pumping periods. The water level in the lower unit (IJ0014) was above that in the upper unit (IJ0013) during injection (greater mounding) and remained higher during periods with no injection. Note that actual groundwater elevations could not be determined (since TOC elevations were not surveyed).

Figure C-3 summarizes the operating history for RW0007, showing the percentage of time that the system was active and the cumulative volume extracted. The categories (x-axis) represent O&M events and are not evenly spaced in time. The cumulative volume extracted as a function of time is presented in Figure C-1 B, which shows a fairly uniform rate over the duration of the field demonstration. Details of the recirculation system operation are tabulated in Table C-2.

A total of 243.4 kgal were recirculated in the upper zone. The effective average flow rate for the system was 0.89 gpm. The system was active for about 53% of the time (active time includes the on/off cycle). Variations in the amount of time the system was active are apparent in Figure C-3; weather, and hence recharge of the solar-powered recirculation system was the main variable controlling system operation.

The upper zone (RW0007) typically operated for somewhat longer than the lower zone (RW0008), averaging 9% more time active. This is attributed to differences in the power required for the pumps to recirculate water in the upper versus lower zone wells; in the lower zone, the system created greater drawdown and consequently needed to lift the water further during pumping, and the greater injection mounding created slightly more resistance due to backpressure. There may have also been minor differences in the efficiency of the solar panels that recharged the system batteries.

Figure C-4 summarizes the operating history for RW0008, showing the percentage of time that the system was active and the cumulative volume extracted. The cumulative volume extracted as a function of time is presented in Figure C-2 B, which shows a fairly uniform rate over the duration of the demonstration. Details of operation are tabulated in Table C-3.

A total of 221.6 kgal were recirculated in the lower zone. The effective average flow rate for the system was 0.81 gpm. The system was active for about 48% of the time (active time includes the on/off cycle). Variations in the amount of time the system was active are apparent in Figure C-4. As with the upper zone system, weather, and hence recharge of the solar-powered system, was the main variable controlling system operation.

PED injection delivered a total of 34,000 gal of amendment fluid. Of this, 17,000 gal was injected into the upper zone, 5,100 gal into the silty clay horizon, and 11,900 gal into the lower zone. Thus the upper zone recirculation volume was a factor of 14.3 greater than the injectate volume, while the lower zone recirculation volume was a factor of 18.6 greater than its corresponding injectate volume. Considering that the design volumes were selected to target 50% of the pore volume in the injection zone, the recirculated volumes in the upper and lower zones represent approximately 7 and 9 pore volume replacements, respectively.

Although it is not possible to determine the actual volume of groundwater involved in the recirculation cells in each sweep zone, some estimates can be made. For the upper zone, the thickness of the saturated aquifer above the silty clay is about 36 feet. Of this, 20 feet was targeted for injection. The extraction well RW0007 has a screened interval of 7 feet, and the injection wells have 10 ft screens, all situated at the base of the upper zone, directly above the silty clay horizon to direct flow across this layer where most of the TCE mass was thought to reside. The relatively short screens in these partially penetrating wells will induce vertical flow components, which will be most prominent near the wells. Horizontal flow is likely not established, since that would require distances beyond about 1.5 times the thickness of the aquifer (i.e., horizontal flow would be expected about 54 ft from an extraction or injection well) and the injection wells are all within this distance of the extraction wells. However, because of the relatively short well screens, the majority of flow is expected to occur in the lower portion of the zone. Thus, the depth interval through which groundwater was recirculated was most likely between 10 and 20 feet. Estimates of the pore volume for various thicknesses and radial distances were calculated (presented in Attachment C-5 to this Appendix). Using a thickness of

15 ft, and a radius of 35 ft, which roughly corresponds to the position of the injection wells, the pore volume of the upper sweep zone was estimated to be 130 kgal, and the volume recirculated in the Main Recirculation Phase corresponds to 1.9 pore volumes. The table in Attachment C-5shows how this estimate varies with the assumed thickness of the sweep zone; if 20 ft thick, the recirculated volume was about 1.4 pore volumes. If just the area within which PED injection occurred is considered, the number of pore volume exchanges is estimated to be about 9.6.

Corresponding estimates were made for the lower sweep zone, as shown in Attachment C-5 for RW0008. The extraction well (RW0008) and injection wells have 10 ft screens, and the PED injections spanned a 15 ft thickness. Assuming a thickness of 15 ft, the pore volume of the lower sweep zone was estimated to be 130 kgal and the volume recirculated in the Main Recirculation Phase was about 1.7 sweep zone pore volumes, or about 8.8 pore volume exchanges of the PED injection area.

These estimates of pore volume demonstrate that considerably more groundwater was recirculated than was initially amended with PED and injected. The fact that extracted water continued to contain donor equivalents indicates that the initial injection was able to supply donor to several multiples of the initial injectate volume.

C.4.1.2 Interim Measure Recirculation Phase

Operation continued unchanged for the Interim Measure Reciculation Phase. Hydrographs for RW0007 and RW0008 for the full period of operation are presented in Attachment C-4. Leveloggers were not deployed in any other wells during this phase.

The operating history for the upper zone (RW0007) is presented in Figure C-3, wherein the purple bars for Time Active indicate the Interim Measure Reciculation Phase. Details of operation are tabulated in Table C-2. The system was active for about 49% of the time, slightly less than during the Main Recirculation Phase. The effective average flow rate for the system was 0.82 gpm, down slightly from the prior phase. The recirculated volume for the upper sweep zone was 240.9 kgal, representing an additional 1.9 pore volumes, or approximately 9.5 additional exchanges of the PED injected area (refer to Attachment C-5 for tabulated estimate).

The operating history for the lower zone (RW0008) is presented in Figure C-4, wherein the purple bars for Time Active indicate the Interim Measure Reciculation Phase. Details of operation are tabulated in Table C-3. The system was active for about 47% of the time, essentially the same as during the Main Recirculation Phase. The effective average flow rate for the system was 0.81 gpm, the same as during the prior phase. The recirculated volume for the lower sweep zone was 239.2 kgal, representing an additional 1.8 pore volumes, or approximately 9.5 additional exchanges of the PED injected area (refer to Attachment C-5 for tabulated estimate).

C.4.2 RECIRCULATION SYSTEM OPERATION - SYSTEM O&M

The groundwater recirculation system operated continuously, with routine O&M inspections to ensure consistent operation of the system (weekly inspections for the first five months, once every 1.5 weeks until the end of the Main Recirculation Phase in Month 7, then biweekly for the Interim Measure Recirculation Phase through until Month 13).

Routine O&M events included the following:

- recording of operational parameters including total volume extracted, extraction flow rates, total operable time (hour meter), battery voltage and charge status, and individual flow rates to the injection wells;
- adjustment of flow rates to injection wells as required to maintain balance of flow between injection wells;
- cleaning and replacing filters as required;
- inspection of visible equipment and tubing runs for leaks or damage and performance of needed maintenance;
- inspection of the solar panels, charge controller and batteries and performance of needed maintenance; and
- periodic retrieval of water level data from the data loggers.

On a few occasions it was necessary to remove a pump for repair. No rehabilitation or re-development of the wells was required. O&M forms are included in Attachment C-3 of this Appendix.

C.4.3 RECIRCULATION SYSTEM OPERATION - GROUNDWATER SAMPLING

C.4.3.1 Groundwater Sampling - Main Recirculation Phase

Throughout the Main Recirculation Phase, groundwater samples were routinely collected to assess the VOC mass flux and evaluate the microbial reductive dechlorination of VOCs.

The extraction wells were sampled weekly for the first month and then bi-weekly for five months thereafter. Samples were analyzed for the parameters in Table 2 of the main document, as detailed in the sampling program in Appendix D. Samples were collected for the assessment of various constituents, namely VOCs, nBA and its hydrolysis product, nBuOH, related fermentation products (i.e., butyrate, acetate, etc. [VFAs]), and the bromide and iodide tracers. To support the interpretation of the data, samples for additional parameters, such as TOC, anions, dissolved metals, DHGs and alkalinity were also collected, along with field parameters (DO, ORP, specific conductivity). Samples for microbial characterization were collected on a monthly basis and archived, with analysis of only the Month 3 and Month 7 samples.

A synoptic survey of the DEM/VAL plot monitoring locations, including extraction wells, bundle monitoring wells, existing site monitoring wells and the far-field monitoring wells (30 wells in total) was conducted at Month 3 (October 2011) and at Month 7 (February 2012), at completion of the Main Recirculation Phase. The samples were laboratory analyzed for VOCs, nBA and nBuOH, VFAs, tracers (Br and I), TOC, DHGs, Sulfide, Anions, Alkalinity, Dissolved Metals and microbial characterization (at select locations). The details of the sampling program are presented in Appendix D and the samples are summarized in Table 2 of the main document.

Results from the Main Recirculation Phase sampling events are compiled and presented in Tables E-1-5 (VOCs, nBA and nBuOH), E-1-6 (DHGs, Anions and Tracers), E-1-7 (TOC, VFAs and nBA), E-1-8 (Dissolved Metals), E-1-9 (Field Geochemical Parameters) and E-1-10 (*Dhc* and *vcr*A) in Attachment E-1 in Appendix E. The VOC data is plotted in Figures 1, 3, 4 and 20 of the main document and in the corresponding time-trend and VOC distribution plots included in Appendix E. The TOC and VFA data is also plotted in Figure 2. The VOC data is used in the plume mass estimates in Figure 21. Attachment E-5 in Appendix E presents the organic carbon data (VOCs, nBA, nBuOH and VFAs) on a molar basis. The laboratory reports from these sampling events are provided in Appendix G.

C.4.3.2 Groundwater Sampling – Interim Measure Recirculation Phase

A somewhat reduced groundwater sampling program was conducted during the Interim Measure Recirculation Phase, from Month 7 until the end in Month 13; the frequency of extraction well monitoring was reduced to monthly sampling for VOCs (including nBA and nBuOH). A synoptic survey was collected in Month 10 (June 2012) and at the end of operation in Month 13 (September 2012). Samples were were laboratory analyzed for VOCs (including nBA and nBuOH), TOC, and DHGs; select locations were sampled for microbial characterization. The far-field wells were removed from the program for Month 13, in accordance with the UIC permit, since the previous two events had shown no nBA at these locations. The sample analyses are listed in Table 2 and in the detailed program in Appendix D.

Results from the Interim Measure Recirculation Phase sampling events are compiled and presented in Tables E-1-5 (VOCs, nBA and nBuOH), E-1-6 (DHGs, Anions and Tracers), E-1-7 (TOC, VFAs and nBA), E-1-9 (Field Geochemical Parameters) and E-1-10 (*Dhc* and *vcr*A) in Attachment E-1 in Appendix E. The VOC data is plotted in Figures 1, 3, 4 and 20 of the main document and in the corresponding time-trend and VOC distribution plots included in Appendix E. The TOC and VFA data is also plotted in Figure 2. The VOC data is used in the plume mass estimates in Figure 21. Attachment E-5 in Appendix E presents the organic carbon data (VOCs, nBA, nBuOH and VFAs) on a molar basis. The laboratory reports from these sampling events are provided in Appendix G.

C.4.4 RECIRCULATION SYSTEM OPERATION - SOIL SAMPLING

Soils samples were collected at the end of the Main Recirculation Phase (Month 7) and at the end of the Interim Measure Recirculation Phase (Month 13). Three soil cores (DPT0346, DPT0347, and DPT0348) were collected on 13 February 2012 and three soil cores (DPT0349, DPT0350, and DPT0351) were collected on 10 September 2012. As shown in Figure 17 (main document), the locations corresponded to the locations (DPT0332, DPT0333, and DPT0334) sampled following the Biomass Growth Phase (03 August 2011), to facilitate comparison over the course of the DEM/VAL. Soil cores were collected using DPT techniques, screened with a PID, and subsampled at various depths based on the PID response and lithology. Boring logs that document the soil lithology are provided with the field forms in Attachment C-2 of this Appendix. A total of 24 samples were selected during the Month 7 sampling event and 22 were selected during the Month 13 event. The samples were submitted to a fixed laboratory for analysis for VOCs, including nBA and nBuOH (refer to Table 2). Select soil samples from the final event in Month 13 were analyzed for *Dhc* and *vcr*A (data not reported herein). Soil IDW was contained in properly labeled 55-gallon drums which were stored on NASA provided spill pallets secured with cargo straps.

The results from the soil sampling events are compiled and presented in Table E-1-1 in Attachment E-1 in Appendix E. Laboratory reports from these sampling events are provided in Appendix G.

C.5 TASK 7 - SYSTEM DEMOBILIZATION

The system was turned over to NASA at the end of the Main Recirculation Phase, to conduct the Interm Measure Recirculation Phase. At the end, the system was simply idled. NASA may decide to perform further remediation at Hot Spot 1 in the future.

		4-May-12	Week 39 O&M
		17-May-12	Week 41 O&M and groundwater sampling (RW wells only)
		7-Jun-12	Week 44 O&M
		21-Jun-12	Week 46 O&M

TABLE C-1. PED DEM/VAL EVENT SCHEDULE SUMMARY

Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Task	Task Name	Date	Activity
6b	Interim Measure Recirculation Phase (cont'd)	26- to 27-Jun-12	Week 47 (Month 10) groundwater sampling (synoptic survey)
		10-Jul-12	Week 49 O&M
		19-Jul-12	Week 50 O&M and groundwater sampling (RW wells only)
		2-Aug-12	Week 52 O&M
		16-Aug-12	Week 54 O&M and groundwater sampling (RW wells only)
		6-Sep-12	Week 57 O&M (final totalizer readings; system on)
		10-Sep-12	Week 58 soil sampling
		13-Sep-12	Week 58 (Month 13) groundwater sampling (synoptic survey)
			** no final readings from time system was turned off

Notes:

1 - Elapsed time is calculated from the number of days between system O&M events; expected to be within a couple of hours.
2 - Hour meter records when power to pump is on. Added to system after the Baseline Flux Assessment phase.
3 - Hour meter reading was adjusted for times when the pump failed but power was available. Comments column notes correction.
4 - Pump operating time (hour meter) is the length of time that the pump operated in this O&M interval.
5 - System flow rate as registered by the flow meter, recorded once per O&M event.
6 - Volume recirculated is calculated from the change in flow totalizer readings between O&M events.
7 - Effective average flow rate is calculated from the volume recirculated and the total elapsed time, including periods of down time.
8 - Average flow rate is the pumping rate, calculated from the volume recirculated and the pump operating time (hour meter). During the Baseline Flux Assessment, since there was no hour meter, the pump operating time was calculated from the estimated time of operation based on the observed flow rate (note 5).
9 - Cumulative volume since start of Baseline Flux Assessment and since start of Main Recirculation System Operation.
10 - Pump operating time (flow rate) is the estimate length of time that the pump operated in this O&M interval, based on the observed System Flow Rate.
11 - Relative percent difference (RPD) between the two estimates of pump operating time, based on system flow rate versus hour meter.
12 - Time Pump Operated is the ratio of Pump Operating Time - Hour Meter to the Elapsed Time. During Baseline Flux Assessment, the Pump Operating Time - Flow Rate is used. A value of 66.6% represents fully operational status, because the system was set to pump for 40 minutes of each hour.
13 - Time Active is the percentage of time during which the system was effectively operating; it includes both the 40 minutes on and 20 minutes off portions of the pump cycle.
14 - Ratio of Time Active compares the Time Active in the upper zone (RW0007) to that in the lower zone (RW0008).

gal - gallon
gpm - gallon per minute
h - hour
kgal - kilogallon
O&M - Operations and Maintenance

a - Wk 22 Correction for Pump Failure (h) =	41
b - Wk 32 Correction for Pump Failure (h) =	156
c - Wk 35 Correction for Pump Failure (h) =	136
d - Wk 46 Correction for Pump Failure (h) =	84

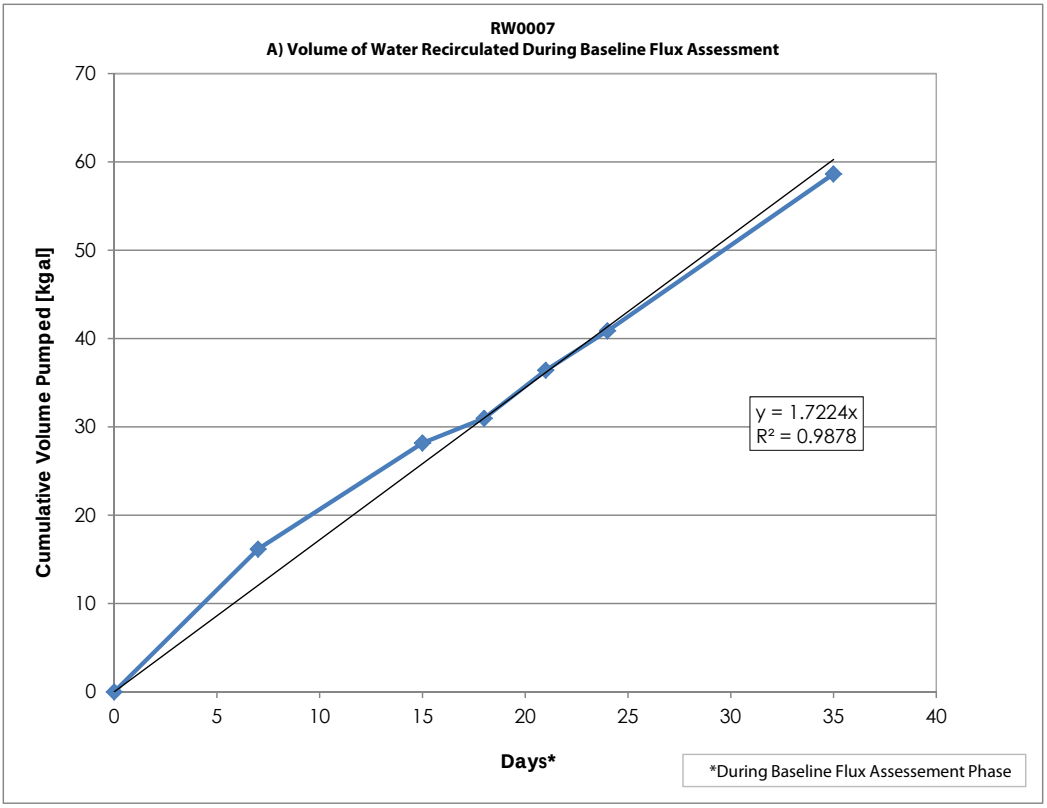
Notes:

1 - Elapsed time is calculated from the number of days between system O&M events; expected to be within a couple of hours.
2 - Hour meter records when power to pump is on. Added to system after the Baseline Flux Assessment phase.
3 - Hour meter reading was adjusted for times when the pump failed but power was available. Comments column notes correction.
4 - Pump operating time (hour meter) is the length of time that the pump operated in this O&M interval.
5 - System flow rate as registered by the flow meter, recorded once per O&M event.
6 - Volume recirculated is calculated from the change in flow totalizer readings between O&M events.
7 - Effective average flow rate is calculated from the volume recirculated and the total elapsed time, including periods of down time.
8 - Average flow rate is the pumping rate, calculated from the volume recirculated and the pump operating time (hour meter). During the Baseline Flux Assessment, since there was no hour meter, the pump operating time was calculated from the estimated time of operation based on the observed flow rate (note 5).
9 - Cumulative volume since start of Baseline Flux Assessment and since start of Main Recirculation System Operation.
10 - Pump operating time (flow rate) is the estimate length of time that the pump operated in this O&M interval, based on the observed System Flow Rate.
11 - Relative percent difference (RPD) between the two estimates of pump operating time, based on system flow rate versus hour meter.
12 - Time Pump Operated is the ratio of Pump Operating Time - Hour Meter to the Elapsed Time. During Baseline Flux Assessment, the Pump Operating Time - Flow Rate is used. A value of 66.6% represents fully operational status, because the system was set to pump for 40 minutes of each hour.
13 - Time Active is the percentage of time during which the system was effectively operating; it includes both the 40 minutes on and 20 minutes off portions of the pump cycle.
14 - Ratio of Time Active compares the Time Active in the upper zone (RW0007) to that in the lower zone (RW0008).

gal - gallon
gpm - gallon per minute
h - hour
kgal - kilogallon
O&M - Operations and Maintenance

a - Wk46 Correction for Pump Failure (h) =	57
b - Wk49 Correction for Pump Failure (h) =	76

FIGURE C-1
VOLUME OF GROUNDWATER RECIRCULATED IN UPPER ZONE (RW0007)



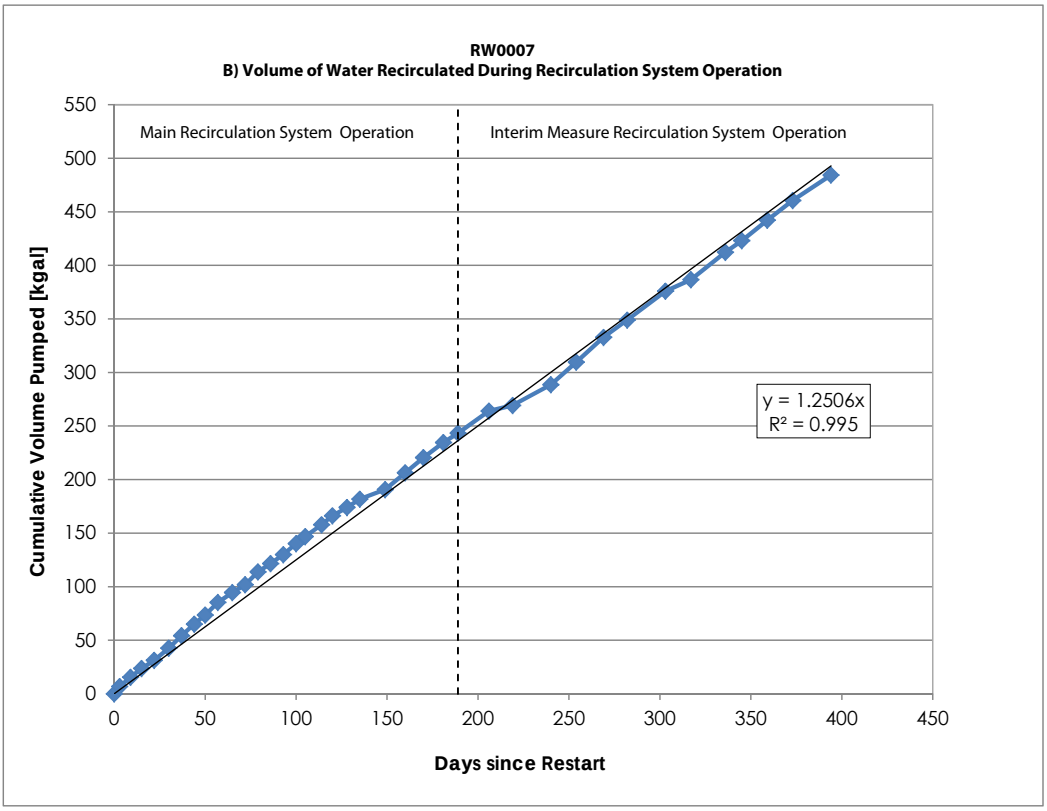


FIGURE C-2
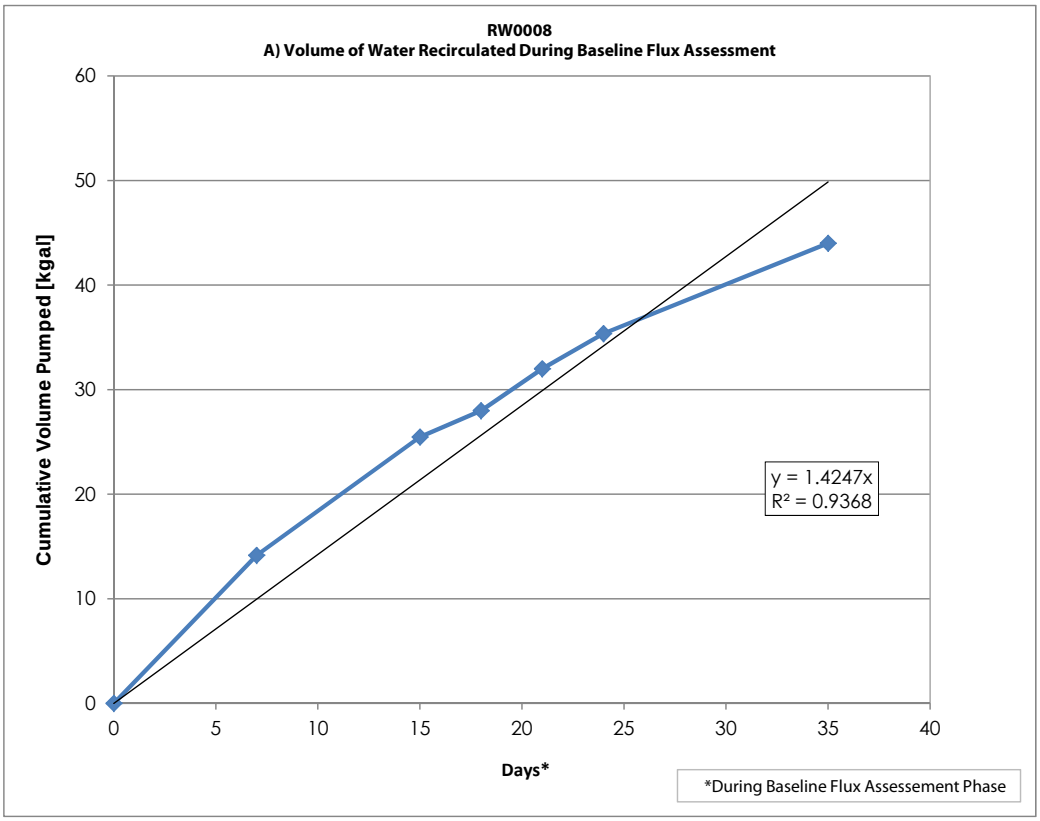
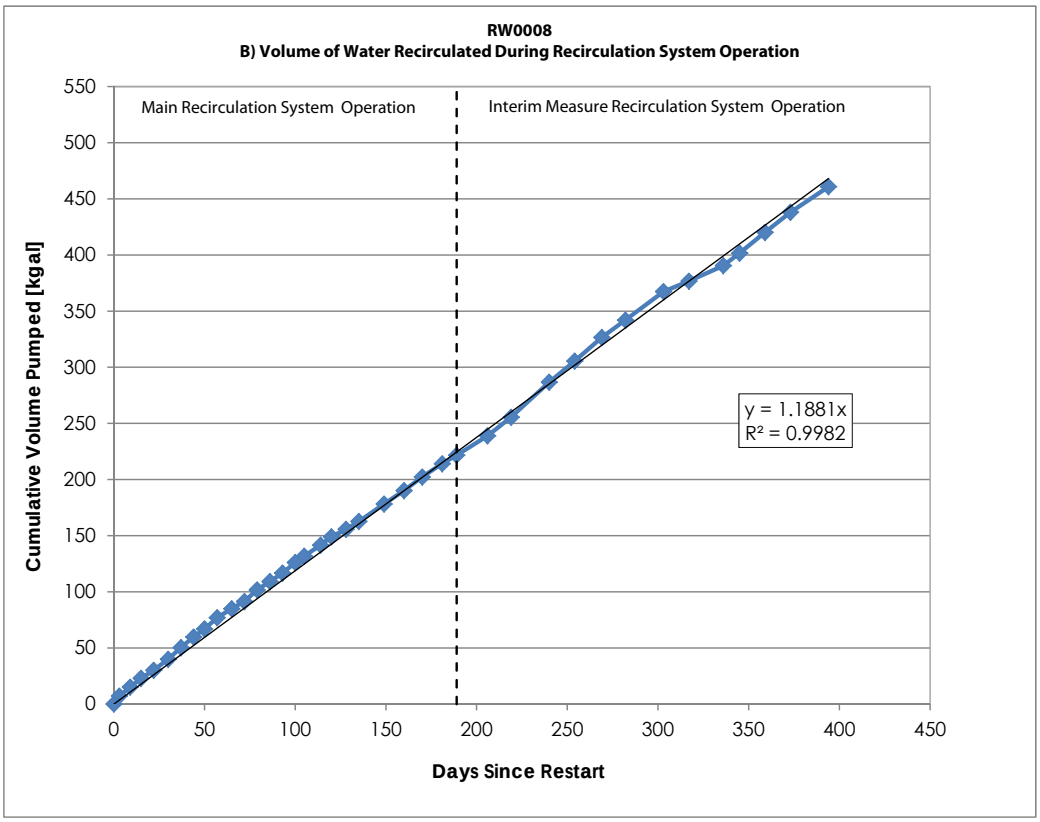
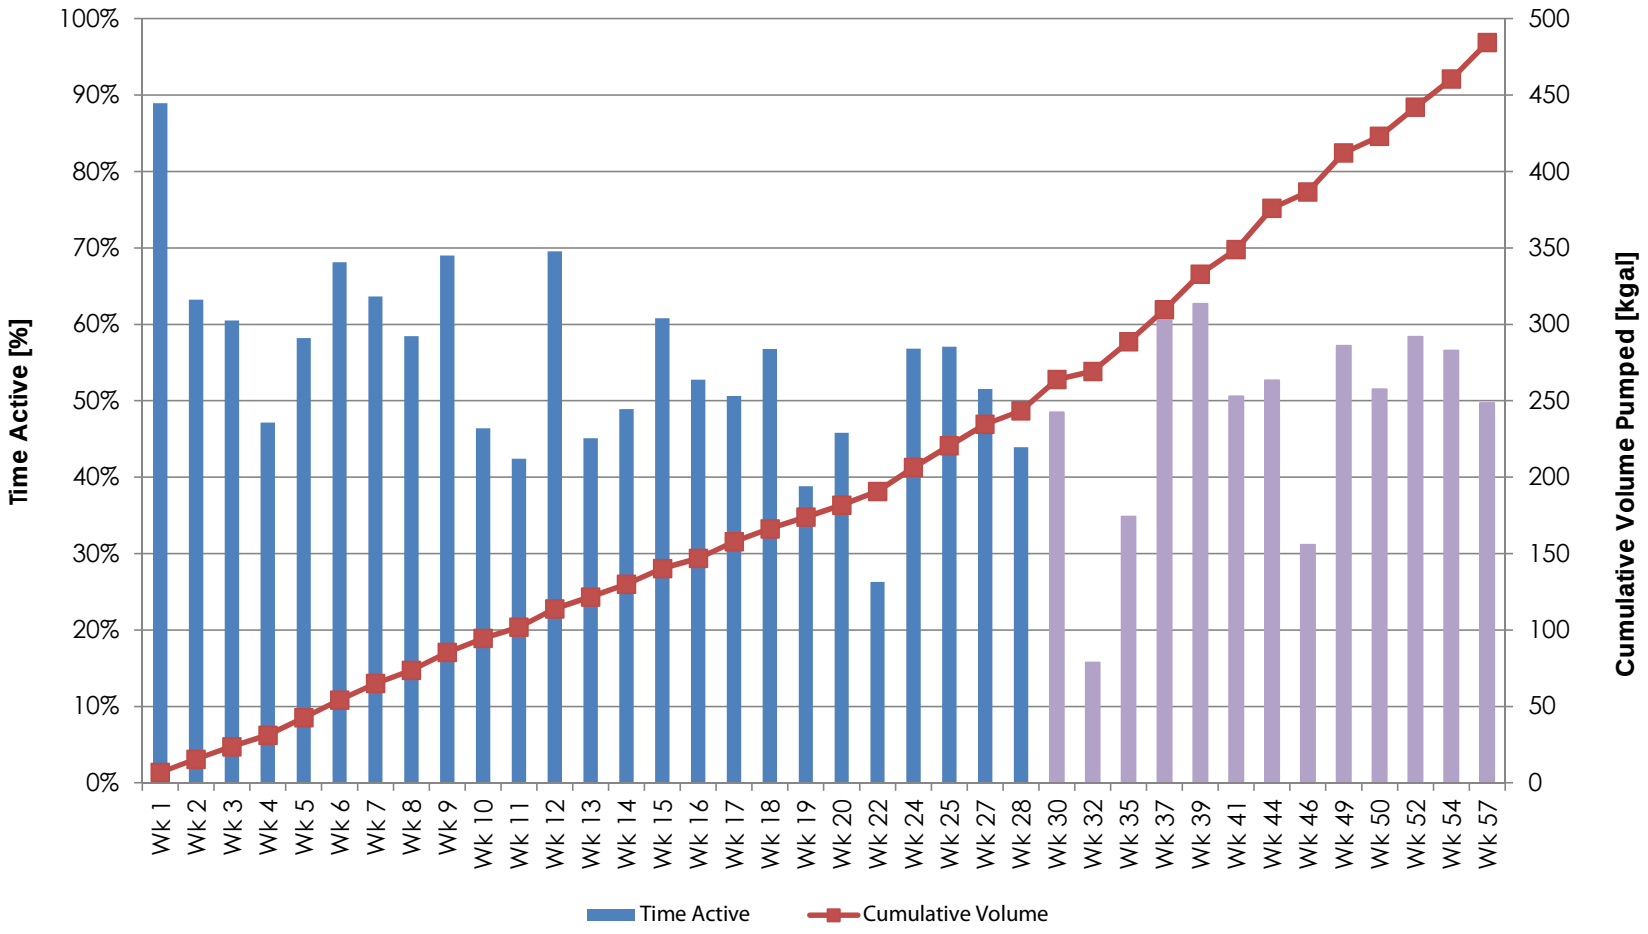
VOLUME OF GROUNDWATER RECIRCULATED IN LOWER ZONE (RW0008)







Notes:

1. Time Active represents the portion of the day in which the system operated. During this time, the pump cycled 40 minutes on, 20 minutes off.

2. The first 28 weeks (blue bars) represent the Main Recirculation System Operation Phase and subsequent weeks (purple bars) represent the Interim Measure Recirculation System Operation Phase.

3. Readings are not evenly distributed over time; less frequent recordings at later time create appearance of greater pumping rate (slope).

Injection Logs ..... Appendix A

Project Summary

Project Name: LC-34

Project Dates: June 20, 2011 - June 28, 2011

Manpower: Mike Mazzarese (Project Manager); Austin Hittinger (Field Tech); Jacob Haldiman (Field Tech); George Lujan (National Director of Safety)

Equipment: One (1) Custom Vironex Remediation Platform, One (1) Support Truck and Trailer

Proposed SOW: Vironex will inject 34,000 gallons of n-Butyl Acetate solution (3,000 mg/L) into 20 locations over a 40 ft injection interval (23 ft to 63 ft bgs). Potassium Bromide (60 mg/L) and Potassium Iodide (140 mg/L) will be added to the injection solutions as specified in the RFP (Bromide in all injection solutions, Iodide in injection solution above the clay layer only).

Project Summary: Injection services were initiated on Monday June 20, 2011. Upon arrival to the site Vironex set up a containment pad and ran hoses for the remediation platform. The platform and mixing totes were grounded due to the explosiveness of the reagent that was being injected. Prior to the injections, a water test was performed to check the line pressure and ensure that there were no leaks in the remediation system. Vironex sustained flow rates between 6 and 8 gpm while averaging 30 to 45 psi throughout the injection process. During this event there were two locations that had to be slowed down due to rising water levels in adjacent monitoring wells: location IP-0011 due to response in IW-0002D1 and location IP – 0018 due to response in RW-0008. This injection event was successfully completed on Tuesday June 28, 2011, one day ahead of schedule.

FIELD FORMS

Geosyntec consultants

DAILY FIELD REPORT

Page 1 of

Project: ~~FA~~ LCJ4 ESTCP PED
Project No.: TR0272
Contractors: EDS - Mike Miller, Cory Love, Carl Leonhardt

Date: 1/17/2011
Task No.:

Work Performed

Well Installation: X - HSA
Soil Borings:
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0715 - arrive @ badging station - pick paperwork
0745 - on site - badging office closed - extra hr for badges
0850 - called duty office to verify on site dig
- tailgate mtg
- FEC on site - dirt in bottom of rolloff
1130 - tornado warning - parked up off of left for lunch - Covered rolloff & removed back.
1245 - back on site - call weather - another tornado warning to be issued & should be in phase 2 - remainder of day
1300 - left site

Plans/Future Activities

- only partially installed PW0022 - got through sand seal will complete tomorrow

Signature/Date 1/17/11

DAILY FIELD REPORT

Page 1 of 1

Project: ESTCP - PED
Project No.: JR0272
Contractors: EDS - Mike Miller, Cory Cave, Carl Lenhart

Date: 11/1/2011
Task No.:

Work Performed

Well Installation: X - HSA
Soil Borings:
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0700 - @ badging station - meet drillers
0720 - on site - call Dig safe - OK to dig
0725 - tail gate meeting
- completed install of IW 0021 & IW 0022
- begin split spoon sample @ RW location b/c cannot have DPT rig & HSA rig in same area due to space concerns
- 1030 - Emily Walkley w/ St Johns River WMD onsite to GPS well locations - we were split spoon sampling location for RW 0008 → inbound mail well permit not issued yet ⇒ cannot install well - left augers in ground @ ~ 20ft BLS & moved to injection well location
1100 - left site for lunch & Joe & I went to POL for spill pallet
1215 - back onsite

Plans/Future Activities

1700 - left site
- installed injection well IJ 0017, IJ 0018, IJ 0019, IJ 0020

Project: LCP4 Date: 1/19/2011
Project No.: TR0272 Task No.:
Contractors: EDS - Mike Miller, Cory Cove, Carl Leonhardt, Chris Phipps, Heath Olson
UD Labs - Glen Parkson

Work Performed

Well Installation:	X	Sampling Soil:	
Soil Borings:	X	Sampling SW/Sediment:	
DPT:		Sampling Monitor Wells:	
Well Inventory:		Sampling Hazardous Waste:	
Other:		Sampling Drums:	

Observations/Issues of Concern

0725 - onsite - EDS onsite
0750 - called duty officer on to dig ⇒ tailgate
0815 - can brake PIDs - 590-000317 MiniRAE Lite
0ppm → 0ppm
100ppm → 100.2 ppm
- 590-000309 MiniRAE Lite
0ppm → 0ppm
100ppm → 100.0 ppm
1030 - auger rig down - sheared pin - Joe & Mike off site to find parts
1200 - Joe & Mike back onsite
~1000 - Emily from JT RWTP onsite w/ permit for recovery wells
1200 - Neil & Joe offsite for lunch & to get spill permit

Plans/Future Activities

* SD0002 & SD0003 ⇒ grain size & TOC from 27-29 ft BLS collected @ 1629
* SD0001 & SD0003 ⇒ grain size & TOC & Tecolids from 33-35 ft BLS collected @ 1646 (grain size from SD0002 only)
~~* SD0003-0410 @ 1320 = DNC sample from~~ NS Did not send sample

Project: LC24
Project No.: TR0272
Contractors: Sam ar Pj

Date: 1/19/11
Task No.:

Work Performed

Well Installation: X
Soil Borings: X
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

- Samples SD1001-044.5-20110119 @ 1656 - DHC
- SD1003 & SD1002 - grain size (SD1002), TOC & % solids from 47 to 48 @ 1657
- " SD1003 & SD1002 - grain size (SD1002), TOC & % solids from 52 to 54 @ 1720
- SD1003 - 043.5 - DHC @ 1657
- SD1003 - 046.0 - DHC @ 1700
- SD1002 - 046.0 - DHC @ 1700
- SD1002 - 043.5 - DHC @ 1657

- left site @ 1745 - back to base
- filled out COCs & organized samples - left at 1915

Plans/Future Activities

- completed 3 DPT soil borings @ locations for DW0001, DW0002, DW0003
- split spoon not completed b/c auger rig broke down
- installed RW0008

DAILY FIELD REPORT

Page 1 of 3

Project: EJTCP PED 4054
Project No.: TR0272
Contractors: FDS - Mike Miller, Cory Cook, Carl Leonhardt, Chris Phillips, Hans Olsen
Date: 1/20/11
Task No.:

Work Performed

Well Installation: X DPT & HSA
Soil Borings:
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0720 - onsite
0730 - tailgate
0755 - called duty officer on to fix
calibrate PID SN# 520-000-309 SN# 520-000-317 (Mini Rae Lite)
0 ppm 0 ppm 0 ppm 0 ppm
100 ppm 99.9 ppm 100 ppm 100.0

- FDS didn't have 1ft PVC riser ⇒ we charged contractor at 58-61 & 51-54 ft wells
* 58-61 ft will have 10ft risr pipe above screen & then two bentonite sleeves
* 51-54 will have 2.5 ft risr pipe & the two bentonite sleeves → 2.5ft risr pipe declined on Monday
- Hovering air around DPT during well install - running PID continuously

Plans/Future Activities

Calibrate turbidity meter - LaMotte 2020

	initial	final
1.0	1.04	1.03
10.0	10.08	10.05

Date: 1/20
Task No.: 1

Work Performed

Well Installation: X Well development
Soil Borings:
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

- Developed injection well IJ0020 - using submersible pump ~1-2 gpm started @ 1316 stopped @ 1343 ~25 gallons - turbid
- Developed injection well IJ0019 - started @ 1344 stopped 1359 ~~1359~~ 15-20 gallons removed - turbid
- ~1430 take DUFZ onsite
- Developed injection well IJ0012 - started @ 1525 stopped @ 1539 - had to move generator & power from battery started @ 1550; stopped @ 1556 ~25 gal - cleared quickly
- Developed injection well IJ0017 - started @ 1600 stopped @ 1616 ~12 gallons

Plans/Future Activities

- Developed injection well IJ0022 started @ 1621 stopped @ 1641 ~20 gal
- ~~Developed injection well IJ0021 started @~~

DAILY FIELD REPORT

Project: ESTCP CC34 Date: 1/27/11
Project No.: TR0372 Task No.: 04
Contractors: EDS (Mike, Coy, Carl, Keith, Chris)

Work Performed

Well Installation: BW0001 E, BW0003BC, BW0003E Sampling Soil: Roll-off
Soil Borings: Sampling SW/Sediment:
DPT: Sampling Monitor Wells:
Well Inventory: Sampling Hazardous Waste:
Other: Develop RW0007 + Bundle wells. Sampling Drums:

Observations/Issues of Concern

0615 Arrive @ Titusville office. Calibrate YSIs & load vehicles
0730 Arrive on site. Both drill crews onsite.
0745 Tailgate safety meeting. Call Pat's office & confirm disposal #
0800 Drillers develop BW0001 clear, while installing BW0003BC+E wells.
Haller Stem drillers begin pad forming at ~~ES~~ injection wells
& set up to develop RW0007
0845 Take composite sample from roll off.
0930 Development of RW0007 finished. ~85 gal removed
1130 DPT drillers take lunch. BW0003BC+E + BW0001E installed.
1150 Take lunch. Return from "empty" labels for empty contaminated drums
from Headquarters. All IS wells padded. Drillers meeting on
EW0008 + 0007 pads
1350 Return to site. Hollow stem drill rig + drillers have left the site.
DPT drillers waiting for bentonite seal to hydrate in final well.
Begin sounding all wells for total depth. Development continues.
1330 All wells installed. Drillers clean site & excavate pad areas

Plans/Future Activities

4x6 pads to be placed over each bundel well set.
1545 Drillers leave site to load truck w/ concrete & make pads.
development continues.
1615 Drum log updated leave site to Titusville office.
1645 CCV of YSIs. Package WS0001 sample for FedEx shipping
1725 ~~AWOS~~ WS0001 samples sent to CAS. End of field day

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Comments:

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

		Add 0.28' to compensate for water level meter probe length									

Notes:
DPT = Direct Push Technology
ft BLS = feet below land surface
mS/cm = milliSiemens per centimeter (or millimhos per centimeter)
NTU = Nephelometric Turbidity Units

DO (mg/L) = Dissolved Oxygen (milligrams per liter)
Temp (°C) = Temperature (degrees Celsius)
TDS (g/L) = Total Dissolved Solids (grams per liter)
ORP (mV) = Oxidation Reduction Potential (milliVolts)

DAILY FIELD REPORT

Page 1 of 1

Project: ~~TR0271.CC39~~
Project No.: TR0272
Contractors:

Date: 2/1/11
Task No.:

Work Performed

Well Installation:
Soil Borings:
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells: BW0001AF, BW0002AF
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0700 - office, calibrate YSI & turbidimeter.
0800 - on site, safety meeting.
0830 - begin sampling
- completed BW0002D-F, BW0001A-C
1130 - lunch
- dropped off JOE's NASA badging paperwork.
- bought 9V batteries

1230 - on-site

1600 - left site to ship samples
- completed BW0001D-F, BW0002A-C
BW0003E, F, A, B

1700 - recal YSI and turbidimeter
1730 - end of day

Plans/Future Activities

0800 - 1000 - GSA pump change out

1000 - on site

- completed sampling: IW00610, IW00710, IW00710D1
- GPS for IJ and BW

1200 - Lunch

1230 - on site

Complete sampling: BW00038 & D, RW00078, IW0076, IW0020, IW00610, IW00700, IW00700D1, IW00209, IW00710, IW00710D1

1615 - left site to ship samples

Plans/Future Activities

1930 - office - COC. end of day.

Sampling Drums:

Observations/Issues of Concern

0650 - at office, calibrate, load truck.
0800 - onsite

completed sampling on: IW0019, IW0015, IW0016, IW0021

IW0023 well found destroyed
- soil @ 5.5 ft. bls

1200 - lunch
1230 - onsite

complete sampling on: IW0020, IW0670 1.

1520 - offsite to ship samples.

1600 - at office, CCV - end of day

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Comments:

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs
If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater
For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs
If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater
For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs
If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater
For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

1. See Table FS 2200-2 on the back of this form

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

DAILY FIELD REPORT

Page 1 of 1

Project: LC34
Project No.: TR0272
Contractors: —

Date: 3/28/11
Task No.: 06

Work Performed

Well Installation:
Soil Borings:
DPT:
Well Inventory:
Other: O&M

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells: Yes
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0630: at office, calibrate YSI, load truck, prepare paper work stopped, got ice from fire station in industrial park on KSC.

0850: on site, JB turn off system, set up for sampling.

sampled wells: RW0007, RW0006, MW0020A, MW0020D.

11:35: called NASA Weather — Phase II for next hour → Lunch

1300: weather is awful — offsite, back to office.

1400: CCV

Plans/Future Activities

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater
For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Contractors: —

Date: 04/07/11
Task No.: 35

Work Performed

Well Installation: ____
Soil Borings: ____
DPT: ____
Well Inventory: ____
Other: ✓ O&M

Sampling Soil: ____
Sampling SW/Sediment: ____
Sampling Monitor Wells: ✓
Sampling Hazardous Waste: ____
Sampling Drums: ____

Observations/Issues of Concern

0730: at office, calibrate YSI / turbidimeter, load truck
0900: at site, begin sampling
- refer to Monitoring Well Sampling Forms for details
sampled Effluent: LC34-EF0003-000.0-20110407 @ 1205 (RW00078)
LC34-EF0004-000.0-20110407 @ 1205 (RW00088)

1440: complete sampling → O&M

PPE in drum 183859 ~60% full
pallet 183397

1530: off site.

Specific Conductance Probe Cleaned? Yes No Disolved Oxygen membrane Changed? Yes No

Comments:

1. See Table FS 2200-2 on the back of this form

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs
If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater
For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Specific Conductance Probe Cleaned? Yes No Disolved Oxygen membrane Changed? Yes No

Comments:

1. See Table FS 2200-2 on the back of this form

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

	3										

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

	3										

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs
If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater
For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Project No.: TR0272
Contractors: EDS, Vironex

Date: 6/28/11
Task No.: 36

Work Performed

Well Installation:
Soil Borings:
DPT:
Well Inventory:
Other: X injection

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0630: at Iron Bartlett at office. Load Vehicle. Travel to Site.
0700: on site. Call Duty Office. OK to dig.
Text Rebecca Dapcato (PM) for morning check-in
Tailgate Safety Meeting.
0745: EDS continue to pull out tools from ground and tremmie grout to surface locations IP0015, IP0017.
0900: Sampled Batch 136 (pumped at 0855)
→ BATCH 136-20110628 [with iodide] @ 0900
Begin injection at IP0018, IP0019, IP0020 at 23-25 FT BLS
1040: Sampled Batch 144 (pumped at 1036)
→ BATCH 144-20110628 @ 1040 [with iodide].
1115-1130: Lunch
1237: Sampled Batch 152 (pumped at 1232)
→ BATCH 152-20110628 @ 1237 [no iodide].
1540: End injection at IP0018, IP0019, IP0020. to 62 FT. BLS.
EDS pull all tools out of ground. Tremmie grout to surface
Vironex Load Equipment

DAILY FIELD REPORT

Project: U34-PRD
Project No.: FR0272
Contractors: EDS, Vironex

Date: 6/28/11
Task No.: 36

Work Performed

Well Installation:
Soil Borings:
DPT:
Well Inventory:
Other: X injection

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

1545: Vironex complete pack up & off site.
1600: EDS clean up site. Build drum pit for GW sampling on Thur. (6/30/11)
1615: Off site. Call Rebecca Deputo (PM) for evening checking.
1700: end of day

Plans/Future Activities

Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0600: Joe Bartlett at Office. Load vehicle. Travel to site
0645: On site. Calibrate YSI.
EDS on site. KBLabs on site
0710: Tailgate Safety Meeting
Call Duty Office. OK to dig.
~~Left~~ Call Rebecca Dporta for morning check-in
0720: EDS Mob to location DPT328. Hand auger to 5Ft BGS.
Begin sampling DPT328.
0855: EDS complete sampling DPT328. Pull tools out. Trimmie grout to surface.
0915: EDS Mob to DPT329. Hand auger to 5 ft BGS. Begin sampling DPT329.
0935: EDS clean & samples.
1030: Complete sampling location DPT329. Pull tools out. Trimmie grout to surface.
1100: EDS Mob. to DPT330. Hand auger to 5 Ft. BGS. Begin sampling DPT330

1. See Table FS 2200-2 on the back of this form

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Comments: Failed DO CCV

Comments:

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

	3										

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs
If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater
For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

	3										

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Pump (Make & Model): Geopump Purge Rate: ~0.1 gpm Water Quality Meter (Make & Model) YSI 556 MPS Water Level Meter: Durham

Time @ Start of Purging: 1032 Time @ End of Purging: 1052 Total Purging Time: 20 min Depth of Pump or Intake Tubing: 038.5 ft. (BTOC)

Water Level: 5.99 Ft. BTOC Total Well Depth: 42 Ft. BGS Reference: TOC Well diameter: 6 in. Volume in well: 61.7 gal.

Screen: 35-42 Ft. BGS.

Correction Factors: (3/4" use 0.02, 1" use 0.041, 2" use 0.163, 4" use 0.653, 6" use 1.469)

Time (hrs)	Cumulative Purge Volume (gal)	Temp (°C)	pH	Conductivity (mS/cm)	Turbidity (NTU)	Salinity (%)	ORP (mV)	DO (mg/L)	TDS (g/L)	Color	Comments
1032	Start	Begin Purge								clear	
1045	1.3	27.06	6.98	2.706	7.25	1.39	-201.3	0.49	1.764	"	
1047	1.5	26.58	7.02	2.740	5.77	1.41	-200.3	0.45	1.781	"	
1049	1.7	26.64	7.00	2.737	3.51	1.41	-209.1	0.40	1.779	"	
1052	2.0	26.61	6.98	2.738	5.59	1.41	-207.5	0.39	1.780	"	

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

		Failed: pH, ORP, and turbidity CCV									

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

		Failed: DO, pH4, pH10, and ORP. CCV									

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

		Failed: pH 7, ORP, turbidity CCV.									

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Contractors: EDS Glen Pennington; Sean Cripe

Date: 8/3/11
Task No.:

Work Performed

Well Installation:
Soil Borings:
DPT: DPT 332, 333, 334
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0725 DMS arrives site, EDS crew is onsite. DMS Conducts tailgate meeting w/ safety discussion. DMS and drilling set up for DPT macro core sampling.
811 Begin macro core sampling. Macro core Sampled by cutting a ½-1" strip from sampler Liner. Strip is removed and immediately Covered w/ aluminum Foil. Foil is punctured w/ a screwdriver. PID meter probe is inserted into foil / soil cavity made by screwdriver. PID responses are recorded on ~~boring~~ DMS boring logs. Cores ~~sampled~~ DMS Screened @ 1' intervals. Soil Samples for Lab analysis were Collected based on Lithology and PID responses.
1015 DPT 0332 Complete, set up for DPT 0333.
1023 ~~DPT 0333~~ DMS Begin DPT 0333.
1230 DPT 0333 Complete; begin setting up for DPT 0334.
1312 ~~DPT 0334 Complete~~ DMS Begin DPT 0334.
1543 DPT 0334 Complete; Begin Grouting DPTs. DMS Collects IDW Samples.

Well Installation:
Soil Borings:
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

1630 Grouting DPTs complete, begin cleaning up & securing site. DMS inventory drums and securing Drum pallets.
1643 Drillers depart site; DMS continues securing drums and securing pallets; Packaging PID meter and finishing Daily notes.
1655 DMS departs site.

1. See Table FS 2200-2 on the back of this form
CAL - Initial Calibration
ICV - Initial Calibration Verification
CCV - Continuing Calibration Verification
Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration
Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)
Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)
If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

		Failed Turbidity, pH4, DO, Sp. Conductance Cal.									

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Sample ID: LC34-RW0008-052.0-20110812 Time Collected: 1048 Comments: VOC + nBA, VFA, Br & I, TOC, Sulfide, MEE, Anions, Alkalinity, Dissolved Metals

~~When using 3/16 in. ID tubing EV= ((0.041) (0.035x tubing length))+(flow thru vol.)=_____gal~~

When using ¼-in. ID tubing EV=(0.0026xtubing length)+(flow thru vol.)=_____gal

0.0026 x 67 + 0.25 = 0.42 gal.

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

1018	1.5	26.48	6.80	2.386	7.78	1.22	-279.9	0.49	1.551	"	

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

1045	1.0	26.40	8.15	2.629	4.84	1.32	-292.7	0.24	1.665	clear	
1048	1.3	26.60	7.89	2.648	2.72	1.32	-288.5	0.12	1.666	"	
1051	1.6	26.59	7.80	2.648	2.46	1.32	-293.8	0.07	1.673	"	

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Sample ID: LC34 - RW0008 - 052.0 - 20110831 Time Collected: 1051 Comments: VOC + NBA, TOC, MEE, VFA, Br + I w/ anions, Sulfide, Dissolved Metals, Alkalinity, Dic + VFA.

CAL - Initial Calibration
ICV - Initial Calibration Verification
CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration
Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)
Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)
If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

1130	1.6	26.42	7.21	2.470	1.31	1.27	-274.8	0.59	1.605	"	

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

1. See Table FS 2200-2 on the back of this form

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Comments:

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

			Fail DO CCV								

Flow cell turned on side during sampling may be cause for higher than normal D.O.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Sample ID: LC34-RW0007-038.5-2011 10 26 Time Collected: 0923 Comments: VOC+nBA, VFA, Br & I, TOL, Sulfide, MEE, Anions, Alk., Dissolved Metals, DHC & VcrA.

When using 3/16-in. ID tubing EV= ((0.041) (0.035x tubing length))+(flow thru vol.)= _____gal

When using ¼-in. ID tubing EV=(0.0026xtubing length)+(flow thru vol.)=_____gal

0.041 x 0.035 x 47 + 0.25 = 0.32 gal

				Fail DO ECV							

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

							DO failed QC				

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

					turbidity not lowering ±5 NTU.						

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Comments:

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

1059	1.5	25.12	7.42	2.587	1.35	1.33	-349.2	0.21	1.681	"	

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Sample ID: LC34-RW0008-052.0-20111110 Time Collected: 1059 Comments: VOC + nBA, VFA, TOC, MEE, Dissolved Metals, Anions w/ Br & I, Alkalinity, Sulfide.

When using 3/16-in. ID tubing EV= ((0.041) (0.035x tubing length))+(flow thru vol.)= _____gal

When using ¼-in. ID tubing EV=(0.0026xtubing length)+(flow thru vol.)=_____gal

0.041 x 0.035 x 62 + 0.25 = 0.34 gal

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Comments:

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Sample ID: LG34-RW0007-038.5-20111215 Time Collected: 1026 Comments: VOC tmBA, TOC, MEE, VFA, Sulfide, Dissolved Metals, Brd I w/ Anions, Alkalinity, DNC & VCrA.

1. See Table FS 2200-2 on the back of this form

CAL - Initial Calibration
ICV - Initial Calibration Verification
CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration
Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)
Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)
If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Monitoring Well Sampling

Site: LC34 Project No.: TR0272A Task: 38 Date: 1/26/12 Sampled By: J. Bartlett

Station (Well ID): RW0007 Purge Method: (Pump) Bailer Pump Type: ___ Submersible (__ Teflon __ SS __ Other) X Peristaltic ___ Centrifugal ___ Bladder

Pump (Make & Model): Geopump Purge Rate: ~0.1 gpm Water Quality Meter (Make & Model) YSI 556 MPS Water Level Meter: Solinst

Time @ Start of Purging: 1002 Time @ End of Purging: 1017 Total Purging Time: 15 min Depth of Pump or Intake Tubing: 038.5 ft. (BTOC)

Water Level: 6.13 Ft. BTOC Total Well Depth: 42 Ft. BGS Reference: — Well diameter: 6 in. Volume in well: 61.7 gal.

Screen: 35-42 Ft BGS

Correction Factors: (3/4" use 0.02, 1" use 0.041, 2" use 0.163, 4" use 0.653, 6" use 1.469)

Time (hrs)	Cumulative Purge Volume (gal)	Temp (°C)	pH	Conductivity (mS/cm)	Turbidity (NTU)	Salinity (%)	ORP (mV)	DO (mg/L)	TDS (g/L)	Color	Comments
1002	Start	24.35	7.25	2.004	3.93	1.02	-242.9	~~3.43~~ 2.23	1.302	clear	
1012	1.0	24.69	7.23	1.982	0.95	1.01	-302.8	1.26	1.288	"	
1014	1.2	24.69	7.24	1.987	1.28	1.01	-304.9	1.18	1.293	"	
1017	1.5	24.49	7.23	1.991	0.83	1.01	-259.9	1.06	1.293	"	

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Sample ID: LC34-RW0007-0385-20120126 Time Collected: 1017 Comments: VOC + MBA, TOC, MSA, VFA, Br + I w/ Anions, Alkalinity, Dissolved Metals, Sulfide, DHC, vcrA.

When using 3/16-in. ID tubing EV= ((0.041) (0.035x tubing length))+(flow thru vol.)= 0.32 gal

When using ¼-in. ID tubing EV=(0.0026xtubing length)+(flow thru vol.)=_____gal

0.041 x 0.035 x 47 + 0.25 = 0.32 gal

DAILY FIELD REPORT

Project: LL34
Project No.: TR0272A
Contractors: -

Date: 2/14/12
Task No.: 38

Work Performed

Well Installation:
Soil Borings:
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells: X
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0800: J. Bartlett and O. Sizemore at office. Calibrate instruments (ICV). Load vehicle. Travel to site.
0900: On site. Perform O&M. Turn off system for sampling event.
0930: Begin sampling. For details refer to monitoring well sampling forms.
- pH probe reading out of range. Reset calibration of pH.
1200: O. Sizemore on site. Recalibrate pH - Called Pine Env. - confirmed malfunctioning pH probe. Order new YSI for pick up tomorrow.
1230: Lunch
1300: Off site
1530: at office - pack coolers for shipment
1600: Calibrate instruments (CCV.) pack up YSI for shipment.
1700: end of day.

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

		* pH probe malfunctioning									

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Sample ID: LC34-RW0007-0385-20120214 Time Collected: 1018 Comments: VOC, fuBA, VFA, Brett, TOC, Sulfide, MEE, Anions, Alkalinity, Dissolved Metals, DHC & vcrA

924	2.0	24.77	7.60	.985	2.5	.48	-254.1	.23	.64	"	"

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

1103	2.0	25.10	7.25	2.531	0.93	1.30	-267.1	.30	1.64	"	"

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

DAILY FIELD REPORT

Page 1 of 1

Project: LC34
Project No.: TR0272
Contractors: GPE

Date: 2/15/12
Task No.:

Work Performed

Well Installation:
Soil Borings: DPT 346, 347 & 348
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

0725 Met drillers @ Badging Station, mob to Site.
0745 Arrive Site; PMS Conducts tailgate meeting w/ Safety discussion. Drillers decon & Set up DPT 346.
1006 DPT 346 Complete; decon & Set up on DPT 347.
1145 DPT 347 Complete; decon & Set up on DPT 348
1424 DPT 348 Complete; Drillers begin grouting 3 Soil borings & Cleaning up Site.
1539 Drillers have grouted all Boreholes & have Cleaned up Site. PMS Begins Securing drum pallet; Drillers depart Site.
1600 PMS departs Site.

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Comments:

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

CAL - Initial Calibration
ICV - Initial Calibration Verification
CCV - Continuing Calibration Verification

Comments: * Failed DO CCV qualified with 2b

* Failed pH CCV qualified with J3

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration
Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)
Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)
If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or, Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C: pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

CAL - Initial Calibration

ICV - Initial Calibration Verification

CCV - Continuing Calibration Verification

Comments:

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration

Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)

Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)

If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Comments:

Allow adequate time for the dissolved oxygen sensor to equilibrate during air calibration
Calibrate specific conductance using at least two standards that bracket the range of expected sample readings (unless readings < 0.1 mS/cm then one standard of 0.1 mS/cm is acceptable)
Calibrate pH using at least two standards (typ. pH 4 and 7) that bracket the range of expected sample readings; always start with pH 7; add a third calibration point if needed (i.e. pH > 7)
If parameter fails to calibrate within SOP acceptance criteria then append sample results with a "J" qualifier

Monitoring Well Sampling

Site: LC34 Project No.: FO 0552B Task: 1240 Date: 8/16/12 Sampled By: J. Barkett

Station (Well ID): AW0007 Purge Method: (Pump) Bailer Pump Type: ___ Submersible (__ Teflon __ SS __ Other) __X Peristaltic ___ Centrifugal ___ Bladder

Pump (Make & Model): Geopump Purge Rate: ~0.1 gpm Water Quality Meter (Make & Model) YSI 556 MPS Water Level Meter: Durham

Time @ Start of Purging: 1250 Time @ End of Purging: 1305 Total Purging Time: 15 min Depth of Pump or Intake Tubing: 038.5 ft. (BTOC)

Water Level: 10.07 ft. BTOC Total Well Depth: 42 ft. BLS Reference: — Well diameter: 1.469 in. Volume in well: 61.7 gal

Screen: 35-42 ft. BLS

Correction Factors: (3/4" use 0.02, 1" use 0.041, 2" use 0.163, 4" use 0.653, 6" use 1.469)

Time (hrs)	Cumulative Purge Volume (gal)	Temp (°C)	pH	Conductivity (mS/cm)	Turbidity (NTU)	Salinity (%)	ORP (mV)	DO (mg/L)	TDS (g/L)	Color	Comments
1250	Start	26.29	7.37	2.596	0.97	1.34	-259.9	0.36	1.709	clear	
1300	1.0	26.19	7.37	2.762	1.82	1.43	-301.3	0.10	1.796	"	
1302	1.2	26.18	7.39	2.793	1.52	1.45	-311.0	0.10	1.825	"	
1305	1.5	26.19	7.42	2.813	1.17	1.45	-323.6	0.09	1.827	"	

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

09:43	1.5	26.0	7.23	.945	1.00	.46	-19.6	.30	.614	"	"

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Time (hrs)	Cumulative Purge Volume (gal)	Temp (°C)	pH	Conductivity (mS/cm)	Turbidity (NTU)	Salinity (%)	ORP (mV)	DO (mg/L)	TDS (g/L)	Color	Comments
908	~~Start~~ 5	26.11	7.76	2.334	2.6	1.20	-272.2	.21	1.52	Clear	—
915	1.0	26.03	7.77	2.338	2.9	1.22	-273.2	.24	1.55	"	—
922	1.5	25.99	7.77	2.339	2.9	1.25	-275.8	.23	1.59	"	—

Note: When purging well with pump or intake tubing within the well screen, purge minimum of 1 equipment volume prior to first field parameter measurements. Take additional field parameter measurements no sooner than 2 to 3 minutes apart, must purge minimum of 3 equipment volume + stabilized field parameters for sampling.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

Note: When purging a well with well screen fully submerged and pump or intake tubing is placed in water column above the screened zone, purge minimum of one well volume prior to collecting first field parameter measurements. Take additional field parameter measurements every ¼ well volume until purging requirements are satisfied.

Note: Three (3) consecutive readings within specified limits are to be obtained for sampling. Temperature: ± 0.2 °C; pH: ±0.2 standard units; Specific Conductance: ± 5.0% of reading; DO is no greater than 20% saturation at field measured temperature; and Turbidity ≤ 20 NTUs

If DO or Turbidity measurements cannot meet the above requirements within 5 well volumes; Temp, pH, Conductivity ranges remain unchanged, however, DO and turbidity must meet the following: DO ± 0.2 mg/L or 10%, whichever is greater; and Turbidity ± 5 NTUs or 10%, whichever is greater

For high turbidity and DO, check flow through cell for air bubbles, which may be causing erroneous readings. Turbidity should be verified visually and with a separate Turbidity meter (if available). All attempts should be made to get the parameters within the specified limits. Check water quality meter calibration before using again.

LC34-IW0076-075.0-20120913

Sample ID: _____ Time Collected: 1102 Comments: TOC, MS/MSD, VOC ~~Filtered~~ pH 7 CCV

J. qualified

When using 3/16-in. ID tubing EV= ((0.041) (0.035x tubing length))+(flow thru vol.)= ~ gal

When using ¼-in. ID tubing EV=(0.0026xtubing length)+(flow thru vol.)= < 5 gal

DAILY FIELD REPORT

Page 1 of 1

Project: LC34	Date: 9/10/12
Project No.: FOO552B	Task No.: 1841
Contractors: EDS	

Work Performed

Well Installation:	Sampling Soil:
Soil Borings: ~~Start~~ DPT 349, 350 & 351	Sampling SW/Sediment:
DPT:	Sampling Monitor Wells:
Well Inventory:	Sampling Hazardous Waste:
Other:	Sampling Drums:

Observations/Issues of Concern

0724 Dms Arrives Badging Station,
0745 Drillers arrive. Drillers badging information is not in the System @ Badging Station. Contact Joe Bartlett.
830 Badging is Complete, mobe to Site.
904 Arrive Site & Set up.
911 Dms Conducts Safety Discussion & Tailgate meeting EDS Crew includes: Mike Miller Driller; Chris Ashburn helper.
918 Drillers set up on DPT 0349.
1207 DPT 349 Complete, Set up on DPT 350,
1308 Phase I
1315 Begin Moderate Rain
1352 Stops Raining.
1450 Begin Phase II. All personnel take cover in vehicles.
1543 Phase 2 over, Continue DPT 350. Note: Lost Sample End Cap in DPT 350
1655 DPT 350 Complete, set up on DPT 351.

~~Plans/Future Activities~~

NOTE: Because Sampler end Cap was lost in DPT 350, only one Sampler available to Complete DPT 351.
1745 Lost 2nd, and only remaining Sampler, End Cap Down Hole. Can not continue DPTs until ~~Second~~ New replaced
Will Continue Tomorrow Am.
1815 Clean up & Depart Site

DAILY FIELD REPORT

Page 1 of 1

Project: FSTOP LC34
Project No.: F00552B
Contractors: FWD

Date: 9/11/12
Task No.: 18 T

Work Performed

Well Installation:
Soil Borings: SB 351
DPT:
Well Inventory:
Other:

Sampling Soil:
Sampling SW/Sediment:
Sampling Monitor Wells:
Sampling Hazardous Waste:
Sampling Drums:

Observations/Issues of Concern

630 Arrive office & prep for Soil & GW Sampling
CR Arrives @ 645 & Calibrates WQMs.
745 Meet Drillers @ Badging Station. Make to Site
810 Arrive Site. Conduct Tailgate meeting w/ Safety discussion.
820 Begin drilling DPT 351 40'-60'. CR Begins GW Sampling
955 Drilling DPT 351 Complete; Drillers begin Grouting borehole & Cleaning up.
1153 Removed data Logger from Trailer.
1302 Removed data logger From RWB
1323 Removed data logger From RW1 - String Broken, had to "fish" out.

Maintenance & Monitoring

Item	Frequency	Completed (yes/no)	Comments or Notes
System operational on arrival (yes/no)[1]	Weekly	No	"load disconnect" light on charge controller suggesting battery charge reached 0%,
System operational on departure (yes/no)	Weekly	Yes	causing the system to shut off until 100% charge reached.
Inspect wiring and connection	Bi-weekly	Yes	
Inspect piping and connections for leaks	Weekly	Yes	system forced ON by turning system off, then on using toggle switches and
Clean filters	Weekly	Yes	disconnecting/reconnecting battery terminals
Collect water levels from injection wells	Monthly	No	
Clean solar panels	As Needed	No	
Clean flow meters	As Needed	Yes	

Extraction Wells				Injection Wells[2]					
	Flow Rate (gpm)	Volume Produced (gallons)	Hour Meter Reading (hours)	Shallow (32-42 ft BLS)	Flow Rate (gph) Initial	Flow Rate (gph) Final	Deep (47-57 ft BLS)	Flow Rate (gph) Initial	Flow Rate (gph) Final
RW0007	2.3	74258	103.4	IJ0013	24	24	IJ0014	27	28
RW0008	2.6	59187	98.9	IJ0015	24	24	IJ0016	30	28

Comments

Water accumulation in IJ17 &18 vault box. Leaking water funneled into vault box through secondary containment tubing. Approx. 5 gallons from vault box poured into IDW drum # 185539. Repaired leak at male-male connector by applying additional hose clamps.

Repaired leaking manifold tubing.

Collected Datalogger data.

Comments

- Upon arrival, RW7 pump was not running. Inspected wiring - ok. Switched source wiring, pump was not responsive.

The pump has reached The end of its useful life. Replaced pump for RW7 with spare.

- Repaired construction fencing.

Comments

Tubing for RW7 had slipped off of 90° located at well top of casing. Will calculate operating time using flow. When reconnected, observed pumping rate to be very slow. Pulled pump, noticed thick cake layer on sediment sock on pump. Washed off and redeployed pump. Flow observed to be normal after cleaning.

Leaking for manifold, replaced cracked tubing segments.

Collected data logger data and removed all data loggers except 2 remaining in RW7 and RW8.

Repaired construction fencing.

Comments

- checked wiring for pump RW7, pulled pumps and tested by hooking directly to battery - noise like motor is trying to turn, but jammed. Replaced pump for RW7.

- checked wiring for pump RW8, pulled pump and tested - unresponsive. Replaced pump for RW8

- repaired leaking manifold tubing.

- readings colleced at 1555.

Injection Wells[2]

Shallow (32-42 ft BLS)	Flow Rate (gph) Initial	Flow Rate (gph) Final	Deep (47-57 ft BLS)	Flow Rate (gph) Initial	Flow Rate (gph) Final
IJ0013	22	24	IJ0014	28	27
IJ0015	25	24	IJ0016	26	27
IJ0017	23	24	IJ0018	28	27
IJ0019	24	24	IJ0020	28	27
IJ0021	24	24	IJ0022	27	27

1. System on a recycle timer set for 40 min/20 min off. If system is off, make sure system is not in 20 min off period.

2. Use flow meters to distribute flow evenly between injection wells. [multiply total flow rate (gpm) by 12 for rate for each well (gph).]

Battery	Voltage (V)	Percent Charge (%)
1a	12.28	56.00
1b	12.24	51.00
2a	12.59	90.00
2b	12.59	90.00

Task that need to be completed during the next scheduled visit

Comments

repaired leaking manifold tubing

marked locations for 12 mth DPT soil sampling

utility locate with Sean O'Brien and Eddie Crayton

Geosyntec consultants

Notes

[1] Field Parameters (FP) are pH, dissolved oxygen, oxidation-reduction potential, specific conductivity, temperature and groundwater elevation

[2] VOCs are Chlorinated Volatile Organic Compounds plus n-butyl acetate (the PED) and n-butanol

[3] VFAs are Volatile Fatty Acids (includes acetic, butyric, lactic and propionic acids)

[4] Tracers include bromide and iodide

[5] TOC is Total Organic Carbon

[6] DHGs are Dissolved Hydrocarbon Gases (i.e., methane, ethene and ethane)

[7] Sulfide is Total Sulfides

[8] Anions include chloride, sulfate, nitrate and nitrite

[9] Alkalinity is Total Alkalinity

[10] Dissolved Metals includes iron, manganese and arsenic

[11] DHC Assay refers to quantitative polymerase chain reaction (qPCR) analysis using the 16S rRNA gene (i.e., SiREM Laboratory's Gene-Trac-Dhc analysis) or the qPCR method used to quantify the Dehalococcoides vinyl chloride reductase (vcrA)

[12] DHC Assay samples were collected monthly and archived

APPENDIX E

DATA SUMMARY

APPENDIX E

DATA SUMMARY

This appendix presents all of the data that was collected during the DEM/VAL, including that collected for the Interim Measure Work Plan (IMWP) for NASA, referred to in this report as the Interim Measure Recirculation Phase.

E.1 SOIL SAMPLING RESULTS

Soil VOC results are presented in Table E-1-1 in Attachment E-1 to this Appendix. The laboratory reports from these sampling events are provided in Appendix G. Samples were collected four times over the course of the DEM/VAL: Baseline, post-Biomass Growth Phase, post-Main Recirculation Phase, and post-Interim Measure Recirculation Phase. The sampling locations are shown in Figure 17 (main document). Baseline samples were collected at the locations of extraction well RW0008 and the three bundle wells. The PED, nBA and its degradation intermediate nBuOH were not detected above the method detection limits in the baseline soil samples that were collected. Baseline organic carbon samples were collected, the fraction of organic carbon (f_{oc}) ranged from 0.00065 to 0.00311 (see Table E-1-2 in Attachment E-1). The highest TCE concentration detected was 22 mg/kg^{wet}, which is well below the 300 mg/kg that is considered representative of NAPL-phase TCE at the site but similar to the 43 mg/kg measured during previous soil coring. This sample was collected from location SB1003 (at BW0001) at a depth of 44 ft BLS, within the silty clay. The maximum TCE concentration in each boring occurred at a similar depth of 44 to 45 ft BLS, although the other locations sampled did not have much TCE.

For the rest of the DEM/VAL, soil sample collection focused on three areas (refer to Figure 17). One was adjacent to the extraction wells (and SB1001) (DPT0332, DPT0346, DPT0349), one was located southwest of BW0001 (and SB1003) (DPT0333, DPT0347, DPT0350), and one was located northeast of BW0001 (and SB1003) (DPT0334, DPT0348, DPT0351).

The samples collected at the end of the Biomass Growth Phase contained higher concentrations of TCE than the baseline samples. The differences reflect natural variability in soil sample collection, as well as the fact that locations and depths were selected to focus on the three selected areas and to try to detect mass within the low conductivity silty clay unit. These data provide a better baseline for comparison with the Month 7 and Month 13 samples. The maximum TCE concentration was 70 mg/kg^{dry}, at 43.5 ft BLS at DPT0332, which is higher than baseline or otherwise previously measured in the area (refer to Section 4.3). Similar results were obtained for samples from 44.0 and 45.5 ft BLS at DPT0333.

In general, it appeared the PED was not present at the sampled locations. The PED, nBA, was only detected in a few locations, at very low concentrations. Minor amounts of nBuOH were

observed in a couple of samples. Nothing could be discerned about the possible partitioning of the nBA into TCE-NAPL.

Similar results were obtained at the end of the Main Recirculation Phase (Month 7), with maximum TCE concentration of 75 mg/kg^{dry} at DPT0348. Again spatial variability appeared to be more significant than changes due to operation of the DEM/VAL. At location DPT0346, the maximum TCE concentration declined from 70 to 4.8 mg/kg^{dry}, while at location DPT0348 the maximum TCE concentration increased from 31 to 75 mg/kg^{dry}, even with samples collected at the same depth. Similar results were obtained at the end of the Interim Measure Recirculation Phase (Month 13), with maximum TCE concentration of 75 mg/kg^{dry} at DPT0350. There was again considerable spatial variability.

Although it is admittedly a very crude approach, all of the results for each event were averaged together to develop an estimate of the mass of TCE and cDCE in soils at the locations sampled. There appears to be some decline in the amount of TCE detected over the course of the DEM/VAL, from the end of the Biomass Growth Phase to the end of the Main Recirculation Phase (Month 7) to the end of the Interim Measure Recirculation Phase (Month 13). Note that baseline is quite different because it represents a different set of locations. However, the analysis is not very robust, given the observed degree of spatial variability.

Average Soil Concentrations (mg/kg)

	TCE	**cDCE**
Baseline	3.60	2.35
Post Biomass Growth	21.27	2.89
Post Main Recirculation Phase (Month 7)	13.07	5.83
Post Interim Measure Recirculation Phase (Month 13)	10.23	5.70

E.2 TASK 2 – INITIAL BASELINE

Results from the Initial Baseline sampling event are compiled and presented in Tables E-1-5 (VOCs) and E-1-9 (Field Parameters) in Attachment E-1 of this Appendix. The VOC data is included in Figures 3, and 4 (main document) for the extraction wells and the corresponding figures in Attachments E-2 and E-3 for other locations. The results were incorporated into the interpolated TCE distribution presented in Figure 16 (main document). The laboratory reports from this sampling event are provided in Appendix G.

E.3 TASK 3 – BASELINE FLUX ASSESSMENT

Results from the Baseline Flux Assessment Phase sampling events are compiled and presented in Tables E-1-5 (VOCs), E-1-6 (DHGs, Anions and Tracers), E-1-7 (TOC, VFAs and nBA), E-1-8 (Dissolved Metals), E-1-9 (Field Parameters) and E-1-10 (*Dhc* and *vcr*A) in Attachment E-1 of

this Appendix. The VOC data is plotted in Figures 1, 3, 4, and 20 (main document) and in the corresponding time-trend and VOC distribution plots included in Attachments E-2 and E-3. The laboratory reports from these sampling events are provided in Appendix G.

E.4 TASK 4 – INTRODUCTION OF PED AND TRACERS

Results from the batch QC sampling are compiled and presented in Table E-1-3 in Attachment E-1 of this Appendix.

The results from the confirmation DPT groundwater sampling are compiled and presented in Table E-1-4 in Attachment E-1 and an analysis of this data is presented in Table E-4-1 in Attachment E-4 of this Appendix. The laboratory reports are provided in Appendix G.

The results from the monitoring well confirmation sampling event are presented in Tables E-1-5 (VOCs, nBA and nBuOH), E-1-6 (Tracers) and E-1-9 (Field Parameters) in Attachment E-1; this data is also presented in Table E-4-2 in Attachment E-4, where tracer and PED data are presented together to assess recovery ratios. The results are plotted in Figures 1, 3, 4 and 20 of the main document for the extraction wells (and the corresponding figures in Attachments E-2 and E-3 for other wells). The laboratory reports are provided in Appendix G.

E.5 TASK 5 – BIOMASS GROWTH PHASE

Results from the Biomass Growth Phase sampling event are compiled and presented in Tables E-1-5 (VOCs, nBA and nBuOH), E-1-6 (DHGs, Anions and Tracers), E-1-7 (TOC, VFAs and nBA), E-1-8 (Dissolved Metals), and E-1-9 (Field Parameters) in Attachment E-1. The VOC data is plotted in Figures 1, 3, 4 and 20 (main document) for the extraction wells (and the corresponding time-trend and distribution figures in Attachments E-2 and E-3 for other wells). This data is used in the estimates of VOC mass remaining in the DEM/VAL treatment zone over the course of operations (refer to Section E.6.1 and Attachment E-6). The TOC and VFA data is also plotted in Figure 2 (main document). The laboratory reports from these sampling events are provided in Appendix G.

E.6 TASK 6 - GROUNDWATER SAMPLING RESULTS

Groundwater samples collected from the central extraction wells (RW0007 and RW0008) make up the primary data set, which includes field parameters, VOCs, nBA, nBuOH, DHGs, VFAs, alkalinity, anions, dissolved metals, and microbial characterization numbers. Additional data was collected during synoptic events from the entire monitoring well network.

All of the data collected for the DEM/VAL is tabulated in Attachment E-1 to this Appendix, including:

- Table E-1-3 Summary of PED Injectate Batch QC Sampling Results
- Table E-1-4 Summary of PED Injection Confirmation Grab Groundwater Sampling Results - PED, VOCs and Tracers
- Table E-1-5 Summary of Groundwater Sampling Results: Volatile Organic Compounds
- Table E-1-6. Summary of Groundwater Sampling Results: Dissolved Hydrocarbon Gases, Anions & Tracers
- Table E-1-7 Summary of Groundwater Sampling Results: TOC, VFAs and nBA
- Table E-1-8 Summary of Groundwater Sampling Results: Dissolved Metals
- Table E-1-9 Summary of Groundwater Sampling Results: Field Geochemical Parameters
- Table E-1-10 Summary of Groundwater Sampling Results: Dehalococcoides and Vinyl Chloride Reductase

Attachment E-2 to this Appendix presents time-series plots of various analytes for each monitoring well location. For each monitoring location there is a set of four time-series plots, as follows:

A) VOC data using molar concentrations;
B) electron donor results, including nBA, nBuOH, VFA and TOC concentration data;
C) bromide and iodide tracer concentrations through the end of the Main Recirculation Phase (these analytes were not part of the sample program in the Interim Measure Recirculation Phase); and
D) several geochemical parameters, including methane, ethane, sulfate and sulfide concentrations.

Attachment E-3 to this Appendix presents the VOC distribution history for each monitoring well location in the form of a stacked bar chart, which shows how the total VOC concentrations varied over time as well as how the composition varied. These figures show the changes in total VOC concentration that were observed following PED addition.

Attachment E-4 to this Appendix presents several tables and figures used for data analysis. Attachment E-5 presents a summary of the results on a molar concentration basis, including tables and figures used in the analysis. Attachment E-6 presents estimates of the VOC mass remaining in the DEM/VAL treatment zone over the course of the demonstration.

E.6.1 VOC TRENDS

Groundwater samples were analyzed for a suite of VOCs, including TCE and its less-chlorinated breakdown products. These results were used to determine the baseline conditions in the test plots and assess the mass flux over time, including an evaluation of the extent of VOC dechlorination and identification of active degradation pathways. All VOC data collected from

the monitoring wells over the course of the DEM/VAL are presented in Table E-1-5 in Attachment E-1 to this Appendix. This data is also presented in several figures. Figure 3a (main document) presents the VOC data at RW0007 as a time-series, including the Initial Baseline and Baseline Flux Assessment results. Figure 3b (main document) presents the VOC data at RW0008 as a time-series**.** Time-series plots for other monitoring locations are shown in Attachment E-2 in this Appendix. Figures 1a and 20a (main document) show the VOC distribution history for RW0007, while Figures 1b and 20b show the VOC distribution history for RW0008. Attachment E-3 in this Appendix contains similar figures for the other monitoring locations.

Figure 4a and Figure 4b (main document) illustrate a quantitative analysis of the extent of dechlorination for RW0007 and RW0008, respectively. The extent of reductive dechlorination in a sample was characterized by calculating the fraction of chlorine removed from the equivalent concentration of TCE (calculated as the sum of the concentration of all chloroethenes and ethene) using the following equation, modified from Hood et al. (2008):

$$\text{Dechlorination Score (\%)} = \left(1 - \frac{3[TCE]+2[cDCE]+2[tDCE]+[VC]}{3([TCE]+[cDCE]+[tDCE]+[VC]+[ethene])}\right) \text{ x } 100$$

where the parentheses indicate molar concentrations and scores of 33%, 67% and 100% represent complete conversion to DCE, VC, and ethene, respectively. Whereas Hood et al. (2008) performed this calculation at a number of locations and presented summary statistics of the dechlorination scores for each sampling event, the values in Figures 4a and 4b are the results of singular analyses for RW0007 and RW0008, respectively, for each event.

The dissolved concentrations of TCE, cDCE and VC were used to estimate the mass of VOCs remaining in DEM/VAL treatment zones over the course of operations. The results are summarized in Attachment E-6. For each synoptic event, the average concentration of each VOC was determined in each of the three zones (upper, middle and lower) using all of the monitoring locations within each zone. Table E-6-1 presents the resulting average concentrations and corresponding mass estimates, calculated by multiplying the concentrations by the estimated groundwater volume in each zone. Estimates of the total mass including sorbed mass were made by calculating compound-specific partitioning coefficients within each zone assuming a linear sorption isotherm dependent on the fraction of organic carbon in the aquifer solids (i.e., $K_d = K_{ow} * f_{oc}$). The total VOC (TVOC) mass estimates are plotted in Figure E-6-1 (see Figure 21 of main document). Note that TVOC mass was estimated using compound mass concentrations rather than molar concentrations and hence are not directly comparable to TCE equivalents.

E.6.2 ELECTRON DONORS

Table E-1-7 in Attachment E-1 presents concentration data for the electron donor species, including nBA, nBuOH, TOC and VFAs. This data is plotted, in molar concentration units, in the 'B' series of figures in Attachment E-2.

In water, nBA can undergo hydrolysis to form nBuOH and acetic acid, both of which can be utilized as electron donors. Butanol is utilized by fermenting organisms to produce butyric acid, acetate and hydrogen. Based on post-injection samples, it appeared that a portion of the nBA was hydrolyzed relatively quickly following injection. Confirmation samples collected about a week after injection showed that significant concentrations of nBuOH had been formed (up to 520 mg/L, with an average concentration of 184 mg/L), representing on average 38% of the PED in these samples (Table E-4-2 in Attachment E-4). At the end of the Biomass Growth Phase, nBuOH was 84% of the total PED found (i.e. nBA plus nBuOH; Table E-4-3 in Appendix E).

Groundwater samples were analyzed for TOC at baseline as an indicator of the concentration of available organic carbon available naturally at the site. Following PED amendment, TOC served a gross indicator of the availability of electron donor in the subsurface. Groundwater samples were analyzed for VFAs to assess the presence of carbon substrates that can serve as electron donors during anaerobic biodegradation of VOCs. VFAs such as acetate can be produced by the metabolism of acetogenic microorganisms while growing on simple carbon compounds such as nBA. These organic acids can then serve as growth substrates and electron donors in VOC dechlorination reactions. Tables E-5-5 and E-5-10 in Attachment E-5, for RW0007 and RW0008, respectively, present the TOC and VFA data together for comparison, including plots that illustrate the mixture of carbon-containing compounds present over time. The TOC data correlated well with the more specific analyses, such as volatile fatty acids, demonstrating that this relatively inexpensive parameter could be used to monitor EISB performance in place of the more expensive, specific analyses, at least some of the time. Acetate and butanoate were the primary VFAs detected and the major components of the TOC. Even at the end of the Main Recirculation Phase, butanoate represented about 25% of the TOC at RW0007 (63% was acetate) and 6% of the TOC at RW0008 (84% was acetate). Persistence of butanoate, particularly in the upper zone, is a benefit of the nBA. The TOC and VFA data is presented in Figures 2a and 2b of the main document for RW0007 and RW0008, respectively.

E.6.3 TRACERS

Table E-1-6 in Attachment E-1 to this Appendix presents concentration data for the bromide and iodide tracers through the end of the Main Recirculation Phase (these analytes were not part of the sample program in the Interim Measure Recirculation Phase). The tracer results are plotted in the 'c' series of figures in Attachment E-2 to this Appendix.

No iodide was ever detected, above the method detection limit, in monitoring locations in the lower zone which infers that there was very little movement of fluid from the upper sweep zone to the lower sweep zone.

During PED Injection Confirmation sampling, some of the DPT grab samples were analyzed for the bromide and iodide tracers. The results are presented in Table E-1-4 in Attachment E-1 to this Appendix. A comparison of PED concentrations to the tracer concentrations was made. The measured concentrations of each were normalized to their respective concentrations in the injectate batches (refer to Table E-1-3). For the PED, the concentrations of nBA and nBuOH (as nBA equivalents) were combined when estimating nBA recovery. Bromide and iodide concentrations were used as measured, since baseline concentrations included a lot of non-detect values, making background correction difficult and prone to introduce errors. The results are presented in Table E-4-1 in Attachment E-4 to this Appendix. The average ratio of normalized nBA to normalized bromide concentration was 0.52, although if the three samples with nBA concentrations below 1,000 µg/L are omitted, the ratio is 0.69. This suggests that relatively less PED is recovered than bromide tracer. Although based on only three sample results, the ratio of normalized bromide to normalized iodide concentrations was about 2.2, suggesting bromide was over-recovered relative to iodide.

A similar analysis of PED concentrations relative to tracer concentrations was performed for samples collected from the monitoring well network on 07 July 2011, a week after PED injection, and on 01 August 2011, following the shut-in period (post-Biomass Growth Phase). The calculations are presented in Tables E-4-2 and E-4-3 in Attachment E-4 to this Appendix. On 07 July 2011, based on 11 samples, the average ratio of the normalized PED to normalized bromide concentration was 0.77, although the ratio of PED to bromide recovered in individual samples ranged from 0.06 to 1.49. On 01 August 2011, the same subset of wells had an average PED to bromide ratio of 0.53 (considering all wells, the ratio was 0.51).

The concentration of bromide in extraction well RW0007 was always higher than that from RW0008, on average by a factor of about 3 (refer to Table E-1-6). Part of the difference may come from the slightly different positions of each extraction well within the PED injected area, such that the capture zone of each might be expected to draw tracer amended fluids slightly differently. However, the greater sustained concentrations at RW0007 suggest that more bromide mass was introduced to the upper sweep zone than the lower.

The TOC and tracer data from each extraction well is plotted in Figure E-4-1 in Attachment E-4. The concentrations of TOC, bromide and iodide are normalized to their average concentrations in the injectate batches. Tracer data was only collected through the end of the Main Recirculation Phase and TOC was only measured quarterly beyond this. At RW0007, bromide was recovered in greater proportion than TOC and iodide. TOC is not expected to be conservative, but it is reasonable to expect bromide and iodide to behave similarly, since they were added together in all injection fluids in the upper zone. One possibility is that more

bromide was delivered to the upper zone than anticipated. This could have occurred if fluids injected into the silty clay or the lower aquifer flowed back along the DPT rods, since this injectate contained only bromide as a tracer. Although there was no indication of this at the time of injection, it would result in additional bromide and nBA being delivered to the upper zone. In the lower zone, at RW0008, the relative recoveries of TOC and bromide were quite similar. Since bromide and TOC (as nBA) were added in constant proportion during injection, any short-circuit flow to the upper zone that might have occurred during injection would affect the normalized concentrations of both equally. It would however result in lower than expected concentrations of both TOC and bromide.

Tracer recovery at the extraction wells is plotted in Figure E-4-2 in Attachment E-4. The tracer concentration data was combined with the extracted volume measurements to estimate the cumulative mass of tracer recovered in extracted groundwater. For the upper zone (RW0007) it is estimated that 11.6 kg of bromide were recovered, which is 3.0 times the bromide mass injected into the upper zone (3.9 kg). At the same time, an estimated 10.7 kg of iodide was recovered, which is 1.2 times the mass injected (9.0 kg). Note that the bromide recovery may have been somewhat higher: the bromide concentrations were background corrected by the average bromide concentrations (1.25 mg/L) observed during the Baseline Flux Assessment. With no background correction, the bromide mass recovered was 12.8 kg (3.3 times the bromide mass injected into the upper zone). In either case, the recovery of bromide was much greater than that of iodide, suggesting either that iodide was not conservative in the system or that extra bromide was introduced. An upper limit on the bromide introduced to the upper zone would be to consider the total mass added to the upper, middle and lower zones. The recovered bromide mass in the upper zone was actually 1.5 times (1.7 without background correction) the total bromide added to all zones (2.3 times the mass amended to the upper and middle zones), indicating that part of the difference is likely attributable to under-recovery of iodide.

For the lower zone (RW0008) it is estimated that 3.1 kg of bromide were recovered, which is 1.1 times the target bromide mass injected into the lower zone (2.7 kg). The ratio need not be the same as in the upper zone, since the actual pore volume of the sweep zones is not known for certain. However, as an experiment, if 40% of the bromide mass targeted to the lower zone is assigned to the upper zone, along with the mass targeted to the silty clay, then the ratio of recovered bromide mass to injected becomes 1.9 for both sweep zones.

Another way to look at the tracer recovery results is to look at when the cumulative mass extracted line crosses the mass added lines in Figure E-4-2 (Attachment E-4). For RW0007, the bromide mass extracted crosses the upper zone mass at about 60 kgal, and the bromide mass for the upper plus silt zones at about 80 kgal. In contrast, the iodide mass extracted line crosses the iodide mass added line at about 190 kgal. It appears that iodide may not have been conservative in the upper test plot.

Average tracer concentrations at the end of the Main Recirculation Phase can be used to estimate how much groundwater has been recirculated relative to the pore volume. This assumes concentrations at the extraction wells are representative of the average concentration throughout the pore volume. Using the mass of bromide injected to the upper zone (3.9 kg) and an average concentration of 7.9 mg/L, it is estimated that the bromide is distributed in a volume of 129.8 kgal. The total extracted volume in the upper zone at this point in operation was 243.4 kgal, which is a factor of 1.9 times greater. Hence, a rough estimate of the number of sweep zone pore volume replacements is 1.9, which is in agreement with the estimate based on area and depth (refer to Section C.4.1.1 in Appendix C). Note that if more bromide mass was actually delivered to the upper zone, then the calculated volume it is distributed throughout would be larger, and the estimated pore volume equivalents would be lower. Using iodide to make the same estimate, the estimated volume in which it is distributed is 316.2 kgal, which is much greater than that estimated using bromide, and yields only 0.77 pore volume equivalents. In the lower zone, the same approach (2.7 kg of bromide, average corrected bromide concentration of 2.8 mg/L) yields a distributed volume of 258.0 kgal, compared to the extracted volume of 221.6 kgal, which yields a ratio of 0.86 pore volume equivalents. The estimated volume containing tracer would be lower if the mass delivered to the lower zone was actually less than target, which would increase the estimated number of pore volume equivalents.

E.6.4 FIELD PARAMETERS

Table E-1-9 in Attachment E-1 to this Appendix presents the field parameter measurement results including pH, ORP, DO, specific conductivity, temperature, turbidity and total dissolved solids, which were measured and monitored for stability during groundwater sample collection to verify proper sampling techniques were followed and that samples were representative. Additionally, parameters such as pH, DO and ORP were used to characterize the prevailing geochemical conditions.

The pH was generally about 7.5, varying somewhat spatially and temporally, but without apparent trends. Average pH in the upper and lower zones was essentially the same. The average pH in the plot appeared to decline slightly at the Month 3 event, but then rose back again. The pH at extraction well RW0007 declined from around 7.5 to as low as 6.75 following nBA addition, gradually increasing again over the period of operation. Similarly, the pH at extraction well RW0008 declined to about 7.0 shortly after recirculation restarted, then gradually rose over the course of operation. Temporary decline in pH is consistent with fermentation of the amended PED.

The ORP was initially negative (average -169 mV in the upper zone and -146 mV in the lower zone), indicating reducing conditions existed prior to PED addition. Following PED injection, at Month 3, the average ORP dropped to -253 mV and -260 mV in the upper and lower zones, respectively. The upper zone ORP averaged -250 mV, -206 mV and -114 mV at Month 7, Month 10 and Month 13, respectively, indicating that the conditions became less reducing during

the Interim Measure Recirculation Phase. The lower zone ORP averaged -264 mV, -265 mV and -248 mV at Month 7, Month 10 and Month 13, respectively, indicating that reducing conditions below the silty clay were maintained throughout the Interim Measure Recirculation Phase.

DO levels were fairly similar throughout the DEM/VAL. The average concentrations were 0.38 mg/L and 0.27 mg/L in the upper and lower zones, respectively, at the end of the Baseline Flux Assessment Phase. The concentrations were similar throughout, until the final sampling event at the end of Month 13 when average DO concentrations were about 1.0 mg/L in both zones.

E.6.5 GEOCHEMICAL INDICATOR PARAMETERS

Table E-1-6 in Attachment E-1 to this Appendix presents the groundwater concentration data for alkalinity and selected anions (chloride, nitrate, nitrite, sulfate and sulfide) that were monitored to support the assessment of geochemical conditions. This table also contains data for the DHGs, including methane, ethane and ethene, as well as the tracer data for comparison. The methane and ethane data, as well as the sulfate and sulfide data for each monitoring location are plotted in the 'd' series of figures in Attachment E-2. Ethene is plotted with the chlorinated ethenes in the 'a' series of figures in Attachment E-2. Nitrate and nitrite were not detected in any of the samples collected.

Chloride is produced during reductive dechlorination reactions; hence increases in chloride concentration might indicate that biodegradation was occurring. However, the baseline chloride concentrations varied considerably with depth in the upper aquifer, and spatially at a given depth. For example, the chloride profile with depth can be assessed at the BW0001 location. At the end of the Baseline Flux Assessment, the chloride concentration in the upper zone increased with depth, from 84 mg/L in the upper interval (BW0001A), to 258 mg/L in the intermediate interval (BW0001B) and to 570 mg/L at the base of the upper aquifer (BW0001C). Even at a given depth, the chloride concentration was quite variable, with values of 570, 687 and 490 mg/L in the 37-40 ft interval (the BW000xC locations) and 642 mg/L at RW0007. Considering this amount of variability, it is not surprising that chloride production could not be confirmed with the data collected. It is noted that the chloride concentration at RW0007 showed a fairly steady decrease over the course of operation, from about 650 mg/L initially to about 400 mg/L at the end of recirculation. This is likely the result of gradual mixing of lower-chloride water from the upper aquifer with water from the base of the upper zone. Indeed, the average chloride concentration in the upper zone was 388 mg/L at the end of the Baseline Flux Phase (April 2011), decreased to 265 mg/L in Month 3 (October 2011), and decreased again, to 157 mg/L in Month 7 (February 2012). Chloride concentrations in the lower zone, including at RW0008, remained relatively constant over the course of the DEM/VAL, with average concentrations of 635, 644 and 604 mg/L at Baseline, Month 3 and Month 7, respectively.

Sulfate concentrations also varied, though not as much as the chloride. At the end of the Baseline Flux Assessment Phase (April 2011), the average sulfate concentration in the upper zone was 43 mg/L compared to 101 mg/L in the lower zone. At Month 3, the average sulfate concentrations had decreased, to 18 mg/L and 44 mg/L in the upper and lower zones, respectively. At Month 7, the average sulfate concentration in the upper zone increased somewhat, to 33 mg/L, while in the lower zone it further declined to 18 mg/L. The decreases in sulfate concentrations were more pronounced at the extraction wells. At RW0007 the sulfate concentration got as low as non-detect during the first three months of operation and then averaged about 3 mg/L for the next four months. At RW0008, sulfate was completely removed at the end of the Biomass Growth Phase (August 2011), rebounded slightly when recirculation re-started and then steadily decreased over the seven months of the Main Recirculation Phase. The decreases in sulfate concentrations were accompanied by increases in those of sulfide. The average concentrations of sulfide increased from non-detect levels initially, to 8 mg/L in both the upper and lower zones in Month 3, to 6 mg/L and 11 mg/L in the upper and lower zones, respectively in Month 7. These trends indicate that the reducing conditions created by the addition of the PED stimulated indigenous sulfate reducing bacteria. Reduction of sulfate to sulfide consumes electron donor but helps to establish suitable redox conditions for the reductive dechlorination process.

Alkalinity increased as a result of PED addition. Baseline alkalinity was 280 mg/L as $CaCO_3$ in the upper zone and 170 mg/L as $CaCO_3$ in the lower zone. At Month 3, the average alkalinity had increased to 500 mg/L in the upper zone and 250 mg/L in the lower zone. At Month 7, the average alkalinity was 360 mg/L and 270 mg/L in the upper and lower zones, respectively. Increased alkalinity is an indicator of microbial activity, since consumption of the applied PED results in production of bicarbonate.

Ethene was present in the groundwater in the upper zone at baseline, at an average concentration of 65 µg/L at the end of the Baseline Flux Assessment Phase (April 2011). However, no ethene was detected in the lower zone or middle silty clay unit. Following PED addition, ethene concentrations in both zones increased as it was produced by the dechlorination reactions. In the upper zone, the average ethene concentration increased over the first ten months of operation, first to 110 µg/L, then 140 µg/L and then 340 µg/L at the Month 3, Month 7 and Month 10 synoptic events, respectively. The average ethene concentration declined somewhat in the last quarter (Month 13), to 220 µg/L. In the lower zone, ethene concentrations also increased significantly over the course of system operation. Here the average concentrations were 50 µg/L, 230 µg/L, 520 µg/L and 570 µg/L for the Month 3, Month 7, Month 10 and Month 13 events, respectively. Ethene production confirmed that complete dechlorination of the parent VOCs (TCE, cDCE) through VC was occurring. Conversion to ethene contributes to the increased flux of VOCs, as can be seen in Figures 20a and 20b (main document) and Attachment E-3.

Ethane was not detected anywhere within the DEM/VAL plots initially, at the end of the Baseline Flux Assessment Phase (April 2011). Following PED addition, ethane was detected at many locations. At Month 3, the average ethane concentration in the upper zone was 25 µg/L, while in the lower zone it was 5 µg/L. The measured concentrations ranged from non-detect to 110 µg/L. This range and average concentration remained similar throughout the course of operation. Ethane is produced by the reduction of ethene, which is produced from dechlorination of TCE, cDCE and VC.

Methane was present in the groundwater from the beginning of the DEM/VAL, in the upper zone more so than the lower, with average baseline concentrations (end of Baseline Flux Assessment Phase) of 80 µg/L and 7 µg/L, respectively. Methane concentrations increased significantly over the course of system operation. In the upper zone, the average methane concentration increased over the first ten months of operation, first to 180 µg/L, then 290 µg/L and then 490 µg/L at the Month 3, Month 7 and Month 10 synoptic events, respectively. The average methane concentration declined somewhat in the last quarter (Month 13), to 280 µg/L. In the lower zone, methane concentrations also increased significantly over the course of system operation. Here the average concentrations were 390 µg/L, 330 µg/L, 830 µg/L and 1070 µg/L for the Month 3, Month 7, Month 10 and Month 13 events, respectively. The highest observed value was 5,800 µg/L, at IW0002D1 at the end of the shut-in period (Biomass Growth Phase). Methane production results from methanogens utilizing the reducing equivalents supplied by the electron donor, likely through acetate fermentation. These microorganisms produce methane as a metabolic product under anoxic conditions, generally after sulfate has been depleted. The methane concentrations suggest that suitably reducing conditions were maintained throughout the DEM/VAL.

E.6.6 METALS

Table E-1-8 in Attachment E-1 to this Appendix presents concentration data for dissolved Arsenic, Iron and Manganese over the course of the DEM/VAL. These species are known to be redox sensitive and are more mobile in their reduced forms. Concentrations were monitored to assess whether the reducing conditions created by PED addition had any effect on these species. Dissolved Arsenic was not detected. Dissolved Iron was observed at relatively low concentrations at a number of locations, although it was not detected in extracted groundwater from either zone after Week 8 (28 September 2011). Concentrations were generally at their highest at the end of the Biomass Growth Phase (01 August 2011), when conditions were likely most conducive to localized dissolution from aquifer solids, since it was one month after PED addition and prior to restarting groundwater recirculation. Dissolved Manganese was observed in most samples at low concentrations of 20 to 30 µg/L, which is below the FDEP GCTL of 50 µg/L. Manganese concentrations also generally showed peak values at the end of the Biomass Growth Phase and then returned to background levels.

E.6.7 MOLECULAR CHARACTERIZATION

Groundwater samples were analyzed for specific microbial genes linked to reductive dechlorination of chlorinated ethenes. The results are presented in Table E-1-10 in Attachment E-1 to this Appendix. Groundwater samples were analyzed via quantitative polymerase chain reaction (qPCR) analysis using the 16S rRNA gene (via the Gene-Trac-Dhc analysis offered by SiREM Laboratory [SiREM]). This analysis determined the presence and abundance of *Dhc* organisms, microbes that are capable of reductive dechlorination of chlorinated ethenes. A separate assay (SiREM's Gene-Trac-VC assay) using the qPCR method was used to quantify the *Dhc vcr*A gene, the gene that codes for vinyl chloride reductase, the enzyme responsible for dechlorination of cis-1,2-dichloroethene and vinyl chloride to ethene. Gene-Trac-VC characterizes the dechlorination capabilities of the detected *Dhc* organisms.

Six locations were monitored over the course of the DEM/VAL, three in the upper sweep zone (BW0001C, BW0003C and RW0007) and three in the lower sweep zone (BW0001E, BW0003E and RW0008). Initially, *Dhc* analyses were performed at all six locations, and *vcr*A was done only at the extraction wells (samples were archived for the other locations). Subsequently, during the Interim Measure Recirculation, the *vcr*A analysis was performed at all six locations.

The baseline samples collected at the end of the Baseline Flux Assessment (April 2011) confirmed that TCE-dechlorinating bacteria are native to the site; however, the number of *Dhc* organisms was relatively low. In the upper zone, the geometric mean of 1.5E+06 gene copies/L suggested that microbial numbers were below the threshold level of 1.0E+07 gene copies/L necessary to support 'generally useful' rates of dechlorination. In the lower zone, the numbers were considerably lower, with a geometric mean estimated to be 3.9E+03 gene copies/L (using half the detection limit where not detected).

The Month 3 samples (October 2011) showed significant increases in *Dhc* numbers, to geometric mean values of 6.7E+07 gene copies/L in the upper zone and 1.6E+07 gene copies/L in the lower zone, increases of 44 and 4,100 times, respectively in response to PED addition. These *Dhc* numbers suggest that useful rates of dechlorination might be supported. Some locations (BW0001C, BW0001E and BW0003E) had not quite reached the threshold level; BW0003C never did reach it, despite a significant increase over baseline. The mean results for Month 7, Month 10 and Month 13 numbers were similar to Month 3 for both the upper and lower sweep zones, indicating that the microbial population was sustained by the electron donors available with the plots.

The *vcr*A results confirm that the detected *Dhc* was capable of degrading vinyl chloride to ethene efficiently. The data from the extraction wells indicates that initially the *vcr*A component made up only about 5% of the *Dhc*, but that over the course of operation the proportion of *Dhc* that contained the *vcr*A component grew to be essentially 100%. This suggests that by Month 10 the

entire *Dhc* microbial population had the capability of degrading vinyl chloride to ethene efficiently.

Notes:

1. ft BLS indicates feet below land surface.
2. mg/kg indicates milligrams per kilogram.
3. U indicates result not detected above method detection limit (MDL).
4. I indicates the result is between the MDL and the practical quantitation limit.
5. L indicates concentation exceeded upper limit of calibration range, estimated value.
6. NA indicates not analyzed.
7. **Bold** indicates the result was detected above method detection limit (MDL).
8. Results not displayed to a set number of significant digits.

[ǂ] The results from analysis of three sample aliquots are reported using slightly different sample depths for the same sample.

[*] Baseline sample data is from a mobile laboratory and is reported on a wet weight basis. All other data is from a fixed laboratory and is reported on a dry weight basis.

	std dev	21	--	1,788,505	--	27	--	--

Notes:

1. mg/L indicates milligrams per liter.
2. µg/L indicates micrograms per liter.
3. nBA/Br is the ratio of n-Butyl Acetate to Bromide
4. nBA/I is the ratio of n-Butyl Acetate to Iodide
5. Br/I is the ratio of Bromide to Iodide
6. U indicates result not detected above method detection limit (MDL).
7. NA indicates not analyzed.
8. -- indicates not applicable
9. **Bold** indicates the result was detected above method detection limit (MDL).
10. Results not displayed to a set number of significant digits.

Notes:

1. ft BLS indicates feet below land surface.
2. µg/L indicates micrograms per liter.
3. * indicates duplicate sample.
4. For primary samples U indicates result not detected above practical quantitation limit (PQL), for duplicate samples U indicates result not detected above method detection limit (MDL).
5. I indicates the result is between the MDL and the practical quantitation limit (PQL).
6. J indicates an estimated value; for primary samples, n-Butyl Acetate values below PQL are qualifed with J.
7. NA indicates not analyzed.
8. **Bold** indicates the result was detected above method detection limit (MDL).
9. Results not displayed to a set number of significant digits.
10. Primary sample results from mobile lab (KB Labs); not certified for n-Butyl Acetate and 1,1,2-Trichlorotrifluoroethane, data should be considered screening level.

Table E-1-5. Summary of Groundwater Sampling Results: Volatile Organic Compounds
Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Location	Sample Date	Screen Interval (ft BLS)	Trichloroethene (µg/L)	cis-1,2-Dichloroethene (µg/L)	trans-1,2-Dichloroethene (µg/L)	Vinyl Chloride (µg/L)	n-Butyl Acetate (µg/L)	n-Butanol (µg/L)	1,1,2-Trichlorotrifluoroethane (µg/L)

Notes:

1. ft BLS indicates feet below land surface.
2. µg/L indicates micrograms per liter.
3. * indicates duplicate sample.
4. I indicates the result is between the method detection limit (MDL) and the practical quantitation limit.
5. J indicates the result is an estimated value based on data validation.
6. Q indicates that the sample was analyzed after the accepted holding time.
7. U indicates result not detected above method detection limit (MDL).
8. V indicates analyte was detected in both the sample and the associated method blank.
9. **Bold** indicates the result was detected above method detection limit (MDL).
10. Results not displayed to a set number of significant digits.

Table E-1-6. Summary of Groundwater Sampling Results: Dissolved Hydrocarbon Gases, Anions & Tracers
Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Notes:

1. ft BLS indicates feet below land surface.
2. µg/L indicates micrograms per liter.
3. mg/L indicates millgrams per liter.
4. Alkalinity is reported as mg/L as $CaCO_3$.
5. J indicates the result is an estimated value based on data validation.
6. Q indicates that the sample was analyzed after the accepted holding time.
7. U indicates result not detected above method detection limit (MDL).
8. NA indicates not analyzed.
9. **Bold** indicates the result was detected above method detection limit (MDL).
10. * indicates duplicate sample.
11. Results not displayed to a set number of significant digits.

Table E-1-7. Summary of Groundwater Sampling Results: TOC, VFAs and nBA
Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Location	Sample Date	Screen Interval (ft BLS)	TOC (mg/L)	Acetic Acid (mg/L)	Butanoic Acid (mg/L)	Lactic Acid (mg/L)	Propionic Acid (mg/L)	Pyruvic Acid (mg/L)	n-Butyl Acetate (µg/L)	n-Butanol (µg/L)

Notes:

1. ft BLS indicates feet below land surface.
2. µg/L indicates micrograms per liter.
3. mg/L indicates milligrams per liter.
4. I indicates the result is between the MDL and the practical quantitation limit (PQL).
5. U indicates result not detected above method detection limit (MDL).
6. V indicates analyte was detected in both the sample and the associated method blank.
7. TOC indicates total organic carbon.
9. VFA indicates volatile fatty acid.
10. NA indicates not analyzed.
11. **Bold** indicates the result was detected above method detection limit (MDL).
12. * indicates duplicate sample.
13. Results not displayed to a set number of significant digits.

Table E-1-8. Summary of Groundwater Sampling Results: Dissolved Metals
Hot Spot 1, LC34, CCAFS / ESTCP Project ER-0716

Notes:

1. ft BLS indicates feet below land surface.
2. µg/L indicates micrograms per liter.
3. J indicates the result is an estimated value based on data validation.
4. U indicates result not detected above method detection limit (MDL).
5. V indicates analyte was detected in both the sample and the associated method blank.
6. * indicates duplicate sample.
7. **Bold** indicates the result was detected above method detection limit (MDL).
8. Results not displayed to a set number of significant digits.

Notes:

1. ft BLS indicates feet below land surface.
2. °C indicates degree Celsius.
3. pH is a measure of the activity of the hydrogen ion.
4. S.U. indicates standard units.
5. mS/cm indicates microSiemens per centimeter.
6. NTU indicates Nephelometric Turbidity Unit.
7. mV indicates millivolts.
8. mg/L indicates milligram per liter.
9. g/L indicates gram per liter.
10. * indicates malfunctioning of probe.
11. J indicates an estimated value (qualified with continuing calibration verification).
12. Results not displayed to a set number of significant digits.

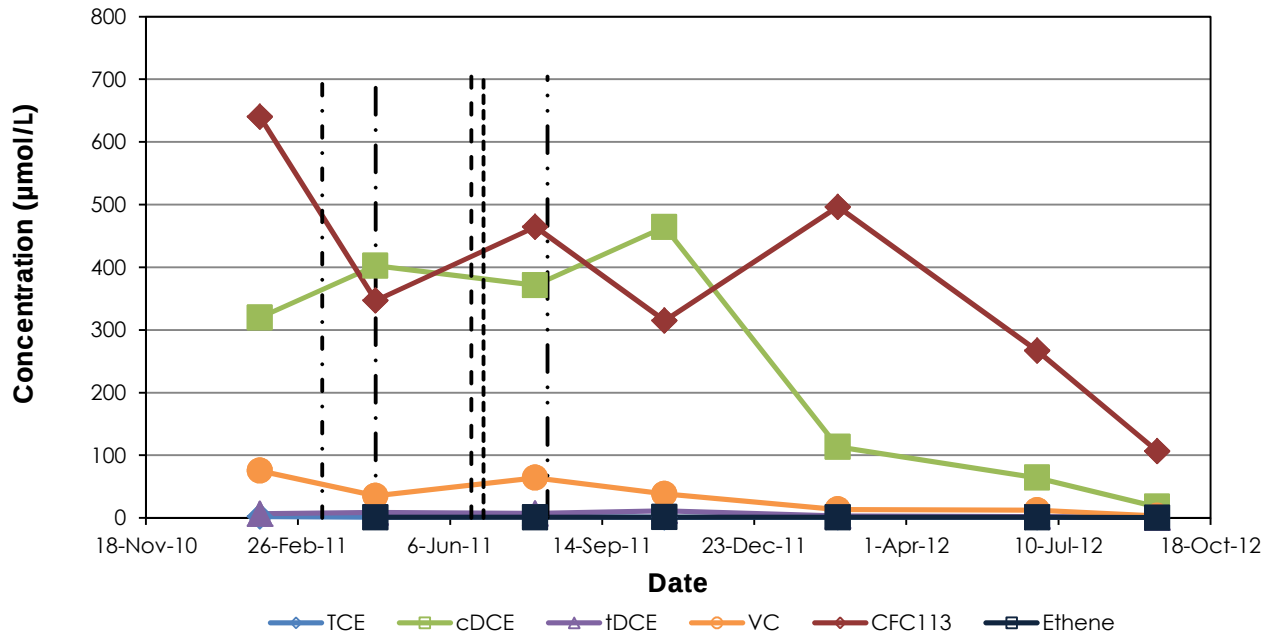
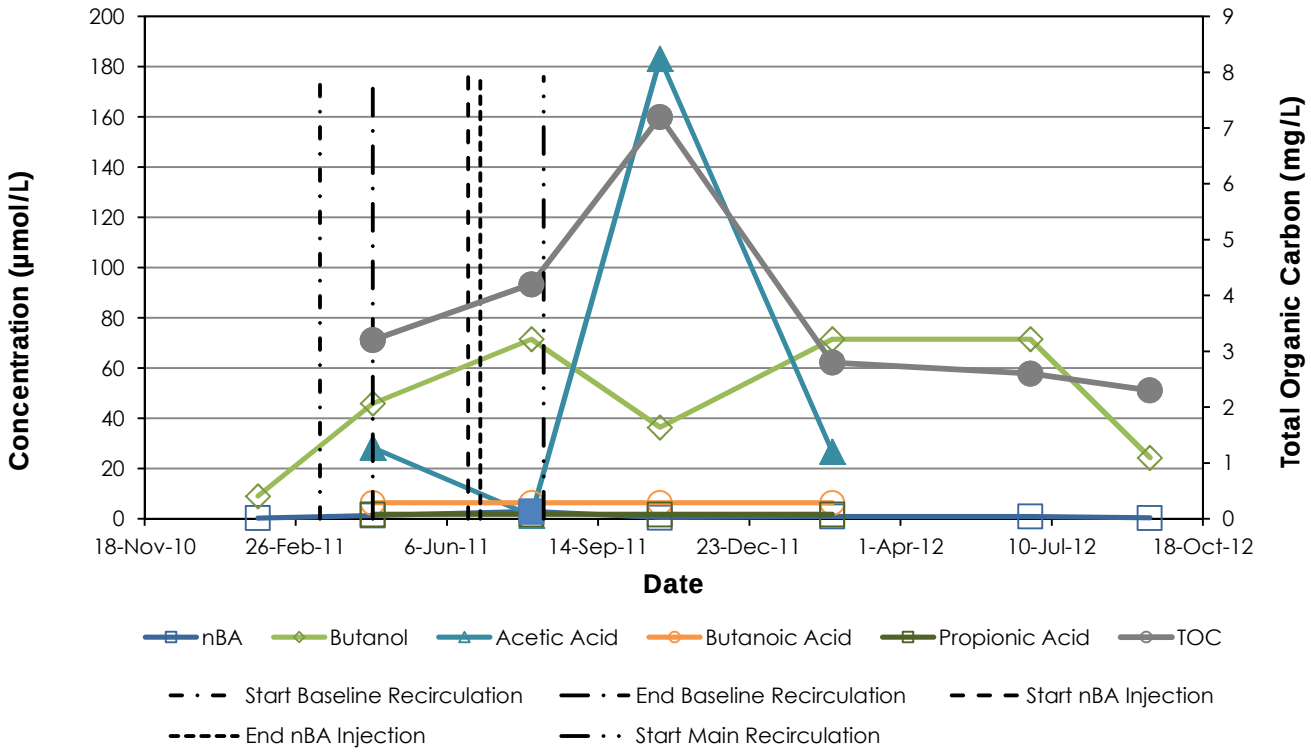
ATTACHMENT E-2

TIME-TREND PLOTS OF DATA BY WELL

A) Volatile Organic Compounds



B) Donors and Volatile Fatty Acids



Notes:
µmol/ L - micromoles per liter
mg/L - milligrams per liter
cDCE - cis-1,2-Dichloroethene
CFC113 - 1,1,2-Trichloro-1,2,2-trifluoroethane
nBA - n-Butyl acetate
TCE - Trichloroethene
tDCE - trans-1,2-Dichloroethene
TOC - Total Organic Carbon
VC - Vinyl chloride
Hollow symbols represent non-detects presented at the method detection limit.

Notes:

1. ft BLS indicates feet below land surface.
2. µg/L indicates micrograms per liter.
3. mg/L indicates milligrams per liter.
4. mol indicates moles.
5. µmol/L indicate micromoles per liter.
6. NA indicates not analyzed or not applicable.
7. ND indicates non-detect.
8. U indicates result not detected above the method detection limit (MDL).
9. nBA - n-Butyl Acetate
10. nBUT - n-Butanol
11. Br - Bromide
12. I - Iodide
13. TOC - total organic carbon
14. $Br^{(0)}$ - Bromide concentration in injectate
15. $I^{(0)}$ - Iodide concentration in injectate
16. $TOC^{(0)}$ - TOC concentration in injectate
17. ' indicates normalized concentration; i.e., $Br' = Br/Br^{(0)}$

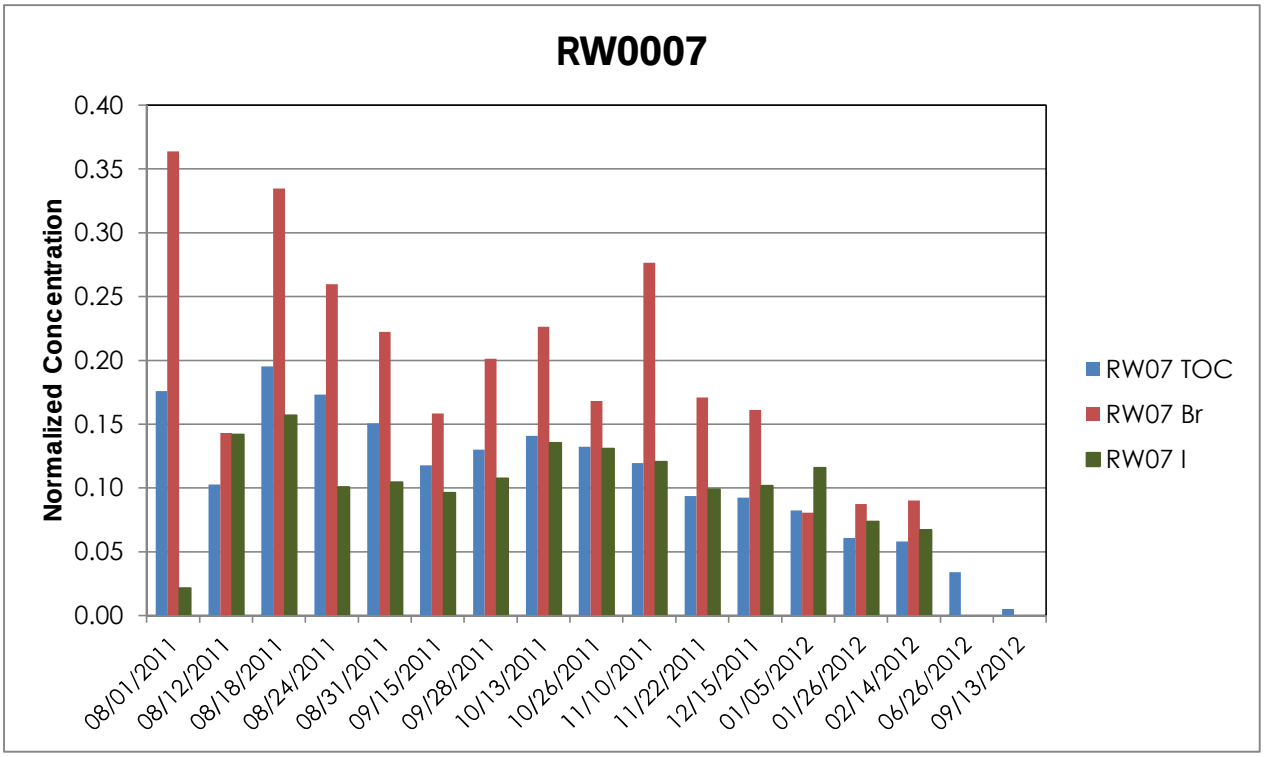
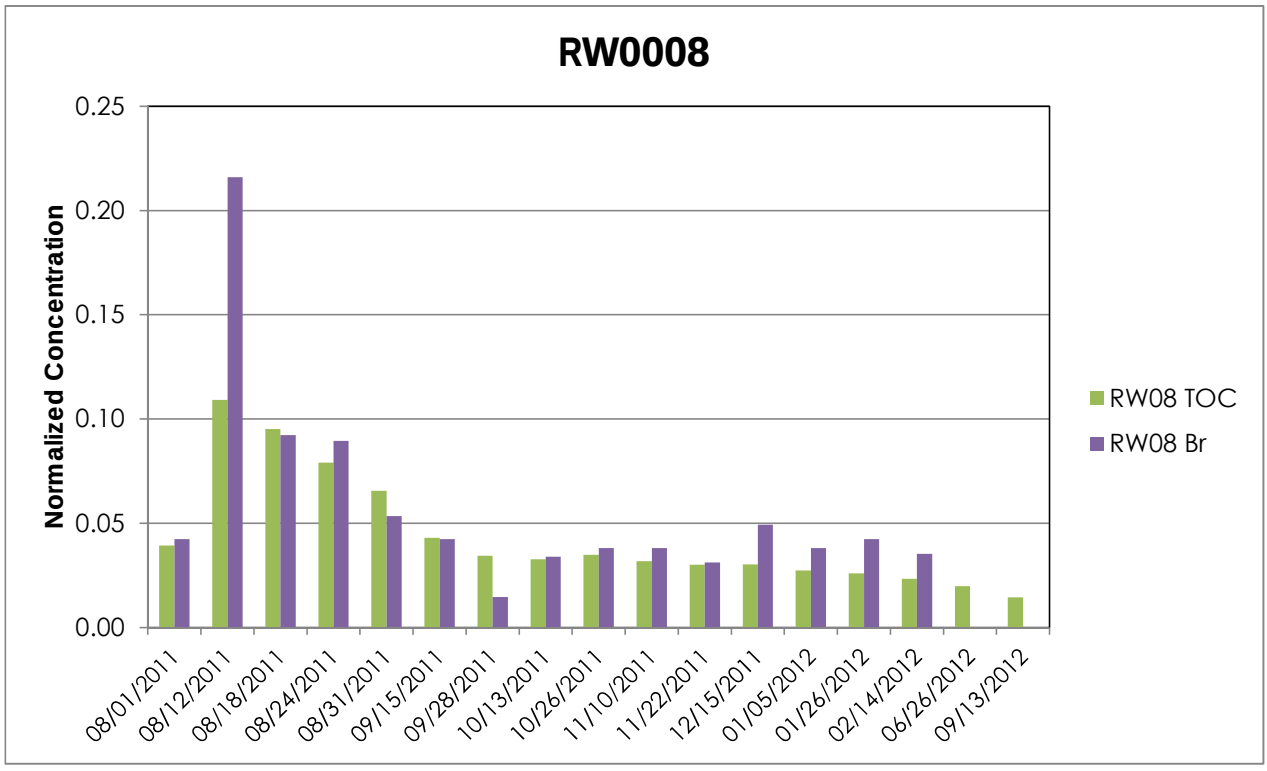
Figure E-4-1. Normalized TOC and Tracer Recovery from Extraction Wells

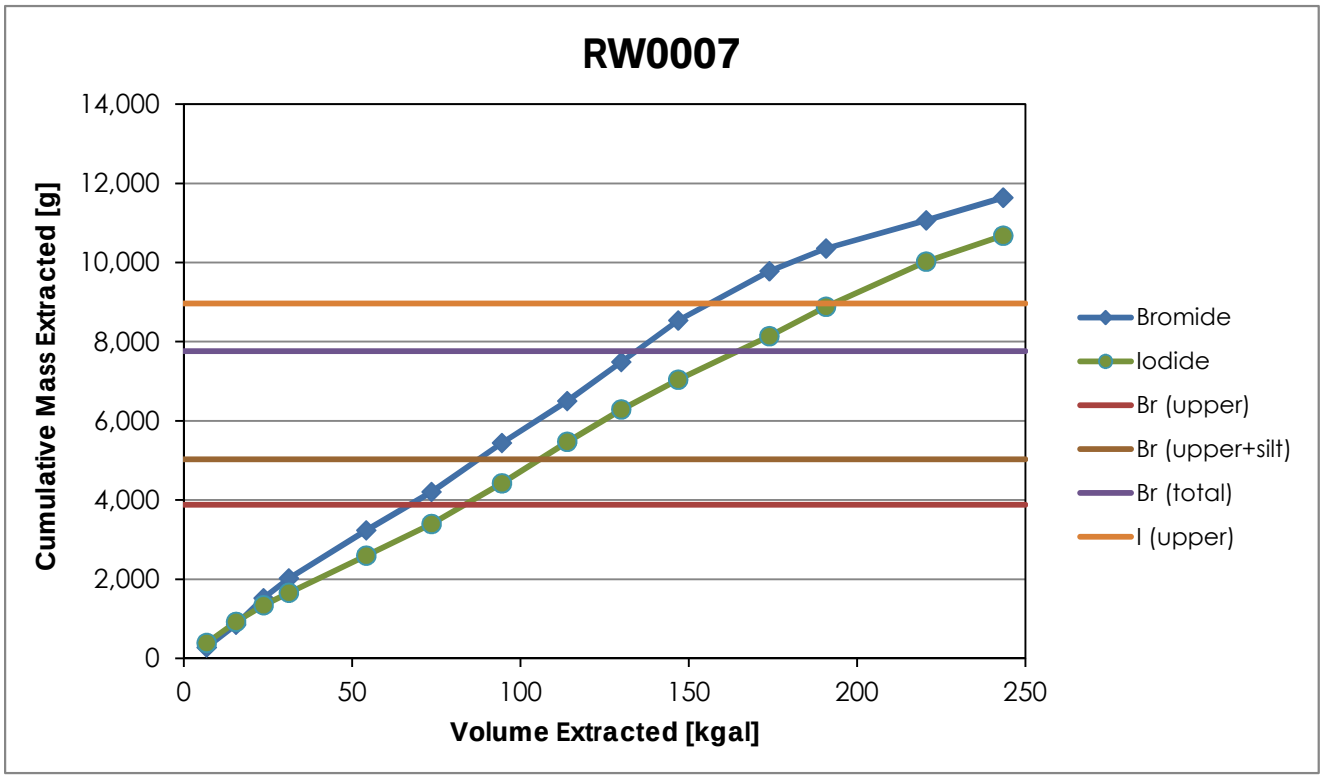


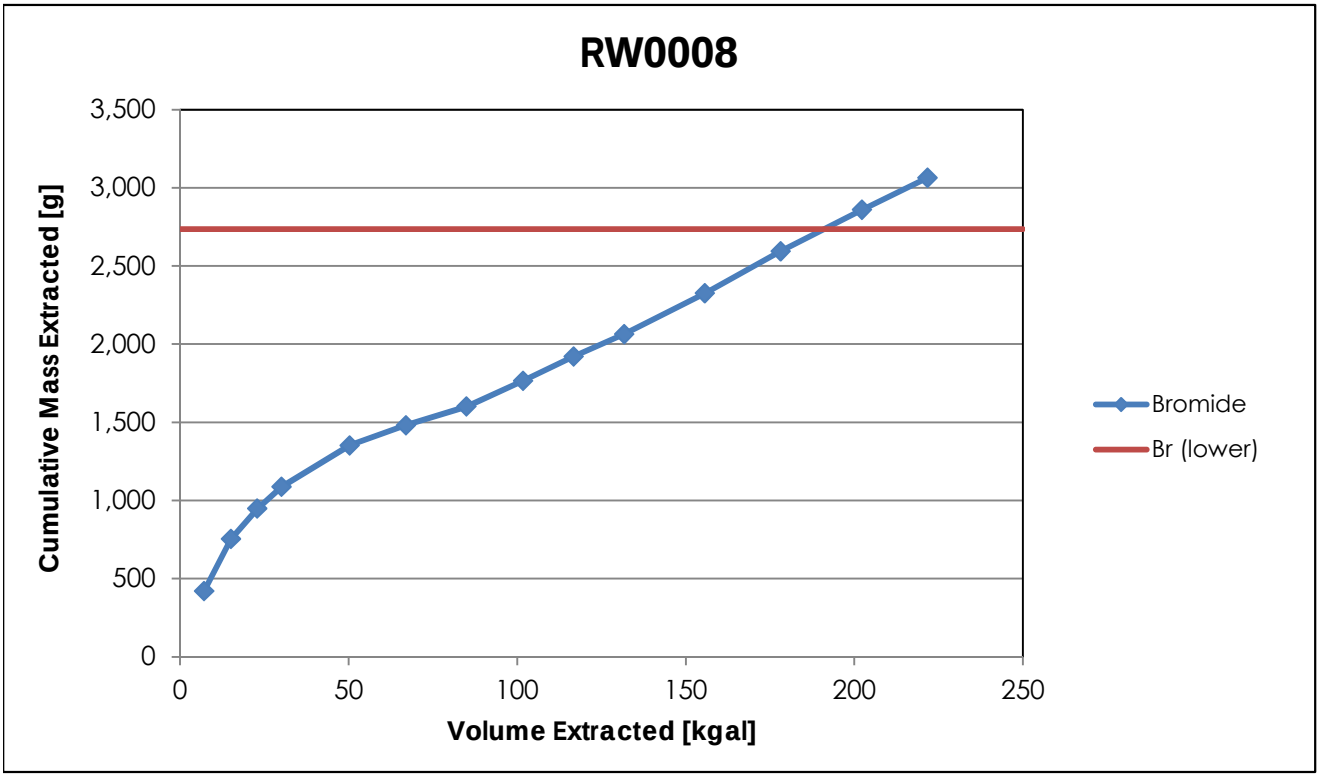


Notes:

1. Normalized concentration is the ratio of the measured concentration to the average concentration in the injectate, as determined from the batch QC samples.

Figure E-4-2. Tracer Recovery at Extraction Wells



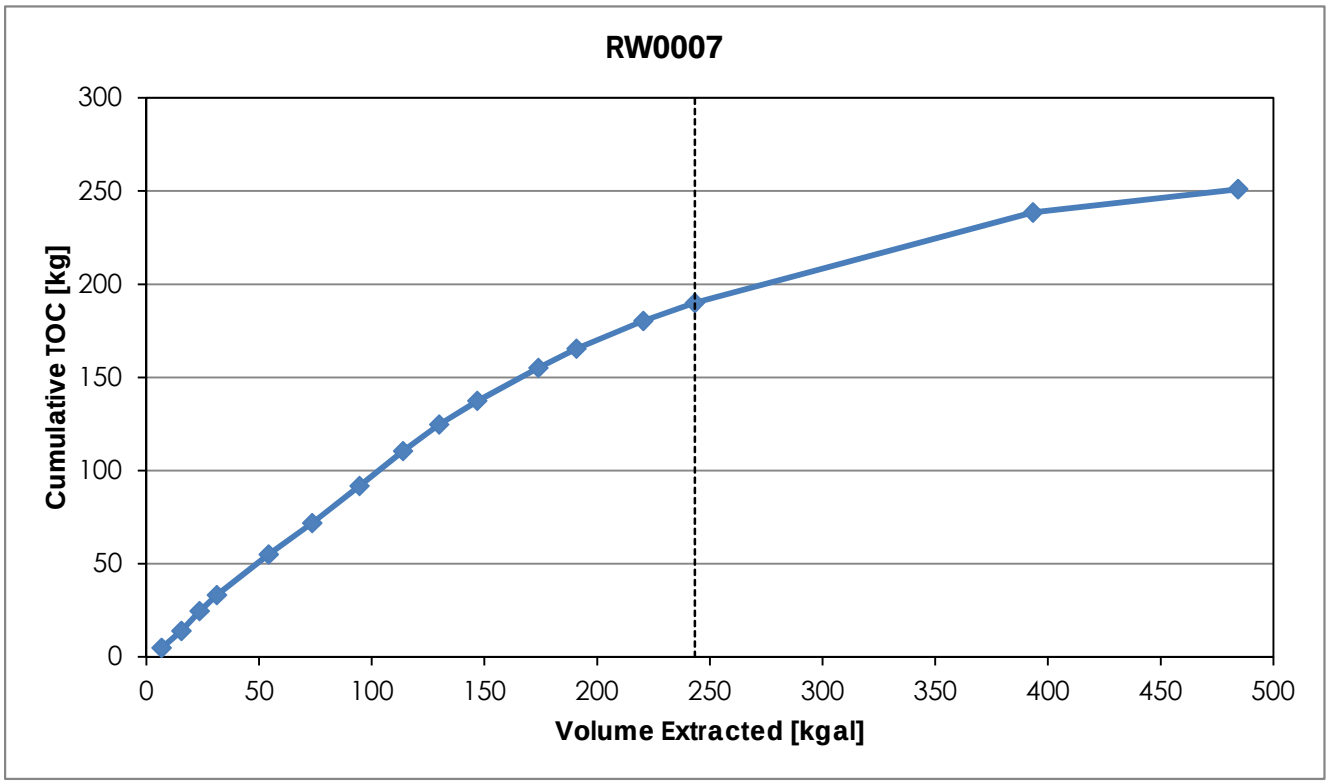


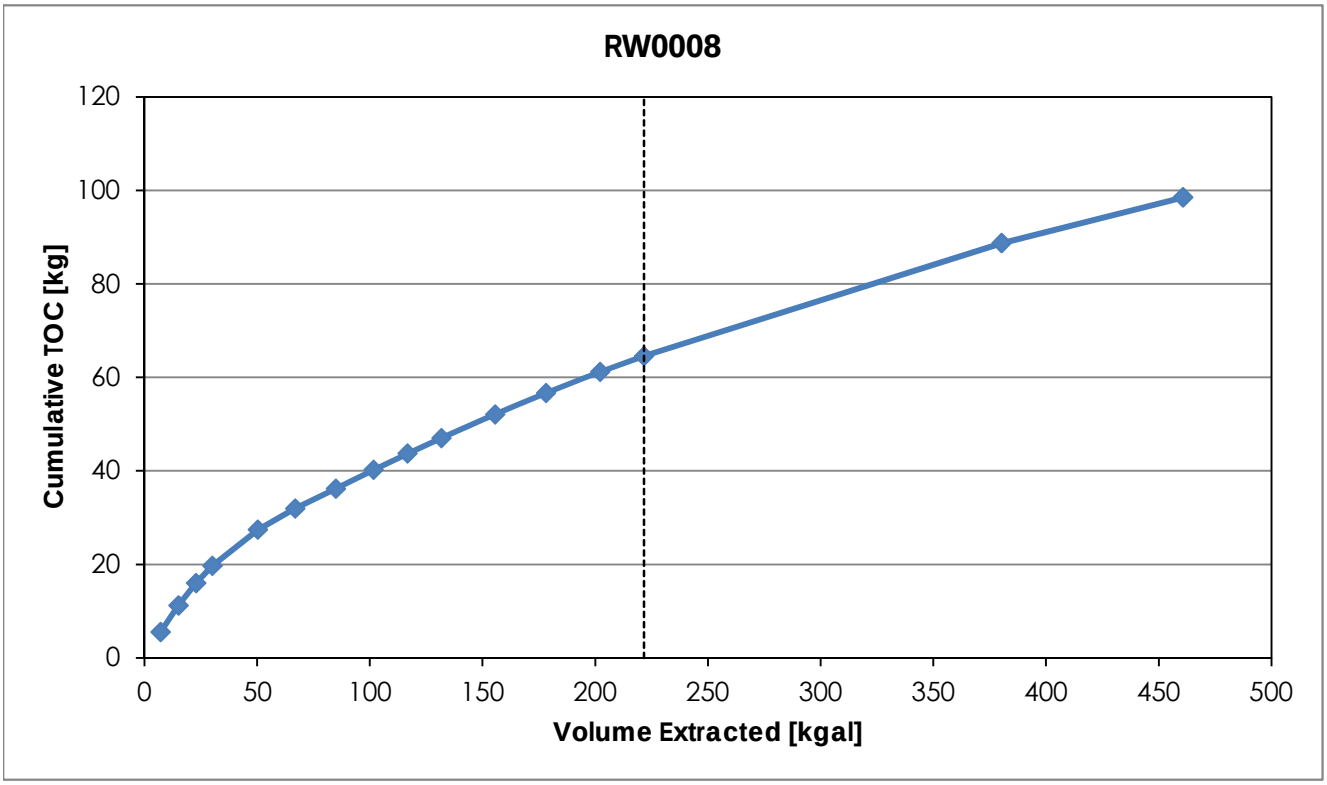
Notes:

Horizontal lines correspond to the mass of tracer added to the injectate targeting the upper zone, middle silty clay zone, and lower zone.

Iodide was only added to the upper zone; the horizontal line is also the total mass added.

Figure E-4-3. Cumulative TOC Recovery at Extraction Wells





Notes:

The total TOC added to the system was 238 kg (from 384 kg nBA). Based on the injection intervals, this corresponds to 119 kg to the upper zone, 35.7 kg to the middle silty clay zone, and 83.3 kg to the lower zone.

Vertical dashed lines mark the end of the Main Recirculation Phase (February 2012).

Notes:

µmol/L - micromoles per liter

mmol/L - millimoles per liter

Values of 0.0 reflect non-detects (or not-analyzed) incorporated in calculations in subsequent tables.

NC - Not calculated, value may be non-detect or not available. See Tables E-1-5 and E-1-6 for complete dataset.

Notes:

µmol/L - micromoles per liter

mmol/L - millimoles per liter

Values of 0.0 reflect non-detects incorporated in calculations in subsequent tables.

NC - Not calculated, value may be non-detect or not available. See Tables E-1-5 and E-1-6 for complete dataset.

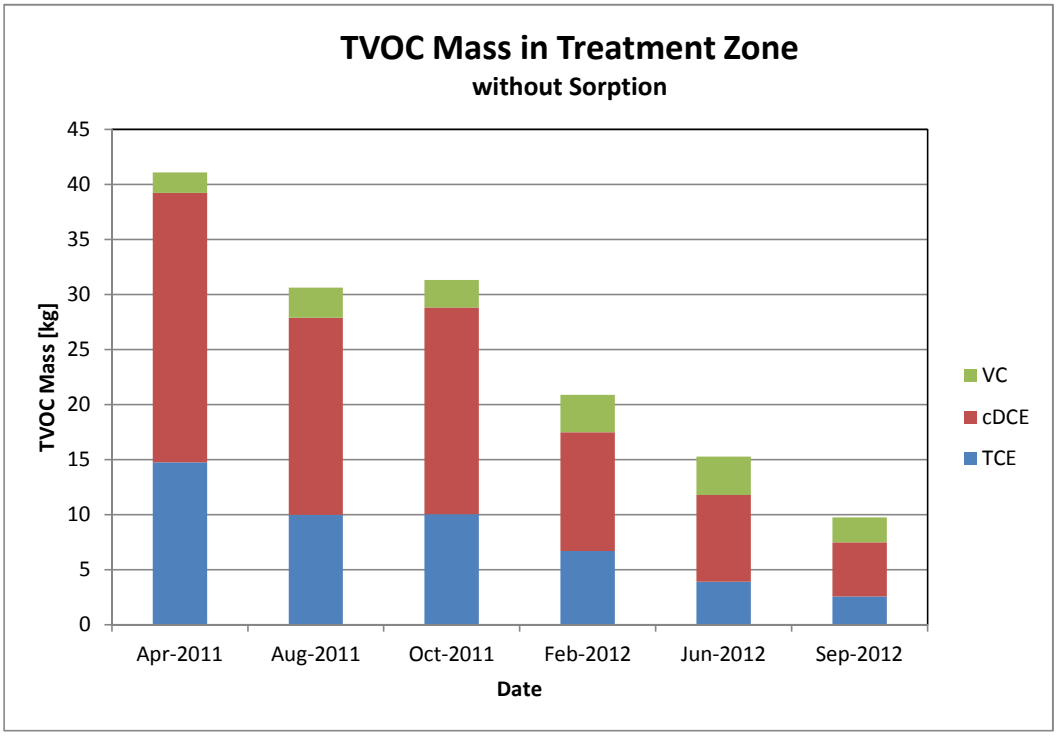
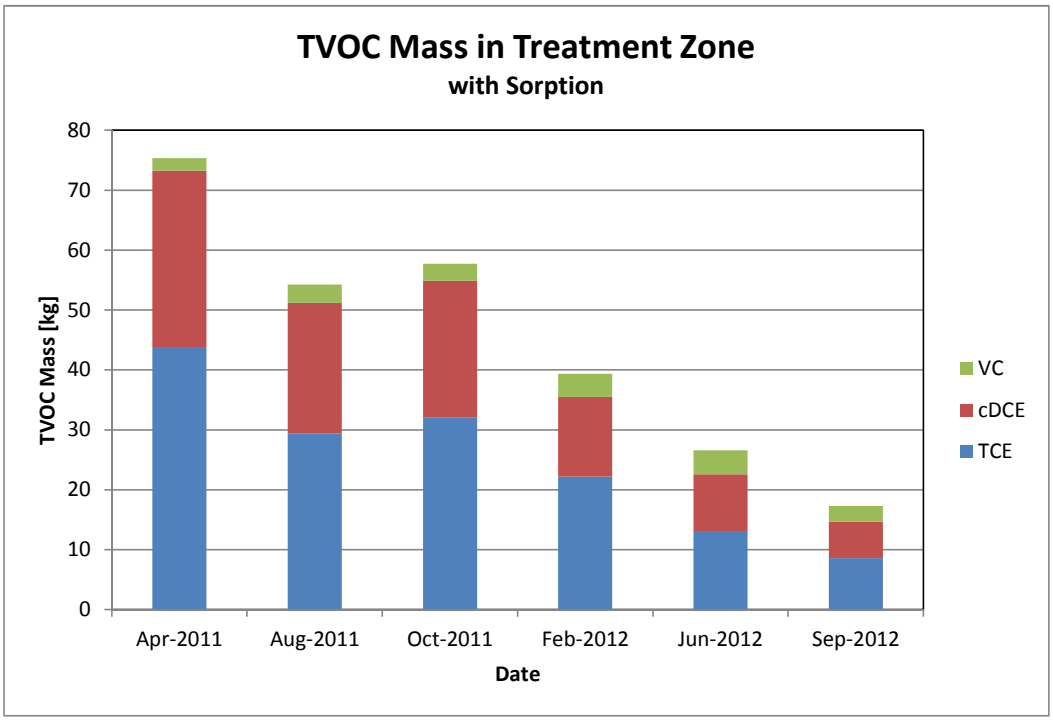
Figure E-6-1. Treatment Zone TVOC Mass Estimates over Operation of the DEM/VAL





Notes:

1. TVOC mass is estimated as the sum of TCE, cDCE and VC (i.e., does not include CFC113).
2. Mass of each VOC in the treatment zone plume is the sum of the estimated mass in each zone (upper, middle and lower). VOC mass in each zone is estimated using the average VOC concentrations at all monitoring locations in that zone and the volume of groundwater in the zone.
3. TVOC mass with sorption is estimated using compound-specific retardation coefficients for each zone.

APPENDIX F

SAMPLE QA/QC

APPENDIX F

SUMMARY OF SAMPLE QA/QC

F.1 CALIBRATION OF ANALYTICAL EQUIPMENT

All analytical instruments were calibrated by the laboratory as required by the standard USEPA methods or the instrument manufacturer's directions. Calibration verification was conducted at least once per day or for each analytical run. Calibration checks using known standard solutions of the analyte of interest were run as necessary during the day and at the end of each sampling session.

Calibration of field equipment was conducted prior to use. At the beginning of each day that measurements were to be taken, field equipment was calibrated according to the manufacturer's instructions using commercially-prepared standard solutions. Calibration verification was re-checked at the end of the day. All instrument calibration information was recorded in the field records.

F.2 QUALITY ASSURANCE SAMPLING

F.2.1 FIELD QUALITY CONTROL

Quality control (QC) procedures for pH, conductivity, DO, ORP, turbidity and temperature measurements were limited to checking the reproducibility of the measurement by obtaining multiple readings (minimum of 3) on a single sample and by calibrating the instruments according to the manufacturers' specifications.

Field sampling procedures included the preparation and submittal of two types of QC samples from the field and were submitted to the lab as "blind" samples in order not to bias the results:

- **Trip Blank:** One trip blank for every cooler containing samples for VOC analyses was prepared with deionized water, preserved to a pH less than 2 pH units using hydrochloric acid, transported to the site, handled like a sample, and submitted to the laboratory for VOC analysis. Exceptions to this were occasionally made for times when only the two extraction wells were being sampled.

- **Field Duplicates:** Two sets of samples from a source were prepared, labeled with unique sample numbers, and submitted to the laboratory without identifying the samples as duplicates (i.e., without indicating which investigative sample the duplicate represents). Field duplicates were collected as sequential samples; to minimize analyte mass loss, particularly of VOCs, homogenization was not conducted with either water or soil samples. Blind duplicates were collected and analyzed for groundwater samples but not for soil samples due to the inherent difficulty of obtaining identical material. The target

frequency of field duplicate collection was one blind duplicate for every 20 environmental samples collected, for all selected analytes. In practice, this frequency was met or exceeded for all analytes except for the tracer compounds bromide and iodide, for which the achieved frequency was one in 33 (3%).

The results of the analyses of these QC samples were used as independent, external checks on laboratory and field contamination as well as the precision of analyses.

No field blanks or equipment blanks were collected. These samples were considered unnecessary since dedicated sample tubing was used at each monitoring location.

F.2.1.1 Field Quality Control Sample Results

No analytes were detected in any of the trip blanks, indicating there was no cross-contamination during sample storage and transport.

The relative percent difference (RPD; refer to Section 2.4.1 below) for all field duplicates for various analytes are presented in Table F-1. For the majority of analytes, the RPD between field duplicates and parent samples was acceptable (RPD $\leq$ 30%). For VOC analyses, 11% to 37% of the field duplicates had RPDs greater than 30% for the analytes of interest (i.e. 2 to 7 samples out of the 19 field duplicates analyzed, considering TCE, cDCE, tDCE, VC, CFC-113, nBA and n-Butanol). Of the instances where the RPD exceeded 30%, nearly half involved an estimated result for the primary sample, the duplicate, or both. When these instances are discounted, the number of duplicates with RPDs exceeding target was 1 to 5 of the 19 analyzed, depending on which analyte is considered. For the non-VOC analyses, all RPDs were within target with the exception of one chloride result. Although in a few cases the RPD was higher than the target RPD, the results are still considered usable for the purposes of this study and the reported values represent estimated concentrations.

F.2.2 LABORATORY QUALITY CONTROL

Samples were analysed by certified contract laboratories. Laboratory Quality Control samples were routinely analyzed as part of their standard operating procedures. These samples consisted of method blanks, matrix spikes (and matrix spike duplicates), and surrogate and laboratory control samples.

Laboratory QA/QC data did not indicate any major data quality issues. For the majority of cases, there were no detections in method blanks, hold times were met, and LCS/LCSD and MS/MSD recoveries and RPDs were within target ranges. In cases where laboratory QA/QC data were outside of data quality targets, the results are considered usable for the purposes of the study and the reported values represent estimated concentrations.

F.2.2.1 Method Blanks

A method (or preparation) blank was prepared at the frequency specified by the referenced method (typically one per analytical batch). The purpose of the method blank is to ensure that contaminants are not introduced by the glassware, reagents, standards, personnel, or the sample preparation environment.

For volatile analyses, an instrument blank was also analyzed during each calibration shift to verify that contaminants are not being introduced by components of the instrumentation or analytical laboratory.

The laboratory has various routine QC checks in place to verify that new lots of glassware, reagents and standards, decontaminated glassware, sample storage areas (including refrigerators), and water purification systems are contaminant-free.

F.2.2.2 Matrix Spikes and Matrix Spike Duplicates

A matrix spike (MS) is a second, extra aliquot of an environmental sample to which known concentrations of target analytes have been added. The MS is carried through the entire analytical procedure, and the recovery of the analytes is calculated. Results are expressed as percent recovery. The MS is used to evaluate the effect of the sample matrix on the accuracy of the analysis.

A matrix spike duplicate (MSD) is a third, extra aliquot of an environmental sample that is also spiked with the same, known concentrations of analytes used for the MS. The two spiked aliquots are processed separately, and the results are compared to determine the effects of the matrix on the precision and accuracy of the analysis. Results are expressed as relative percent difference (RPD) and percent recovery.

One MS/MSD set was analyzed for every set of investigative samples, for the volatile organic analyses (i.e., VOCs, VFAs and DHGs). The MS/MSD was site-specific and, therefore, field personnel were responsible for collecting additional sample volumes to account for the MS/MSD samples. Similarly, for the other investigative samples collected for inorganic parameter analyses (i.e., tracers, anions, sulfide, alkalinity, dissolved metals, and TOC), laboratory QC involved an MS sample and a duplicate sample to assess the reproducibility (RPD).

F.2.2.3 Surrogate and Laboratory Control Sample Recovery

Surrogate standards were added to each organic sample requiring gas chromatography/mass spectrometer (GC/MS) analysis for VOCs in accordance with the particular method being utilized. In some instances the sample matrix may produce interferences that adversely affect recoveries. Surrogate recoveries were monitored to ensure that they met method acceptance criteria. In addition, laboratory control samples (LCSs) are fortified with spike standard solutions containing target parameters of interest. The recovery of these standards was

quantitatively measured during analysis, and historical records maintained on the percent recovery for each sample.

F.2.3 QUALITY ASSURANCE OBJECTIVES

The data quality indicators (DQIs) for this project were precision, accuracy, representativeness, completeness, comparability, and sensitivity (PARCCS). The quality assurance (QA) program addressed both field and laboratory activities. QA objectives for measurement data are expressed in terms of PARCCS. The field QA/QC program was accomplished through the collection of field duplicates and trip blanks. The analytical QA/QC program was assessed through the internal laboratory QC performed, including method blanks, LCS recoveries, surrogate recoveries, and matrix spike/matrix spike duplicate (MS/MSD) recoveries. Data quality acceptance criteria are presented below.

F.2.3.1 Precision

Precision quantifies the repeatability of a given measurement. Precision was determined through the collection of field duplicates and the analysis of MS/MSD samples. Sampling precision was measured through the laboratory analysis of field duplicate samples. Laboratory precision was measured through the analysis of MS/MSD samples, laboratory duplicate samples and laboratory control sample/laboratory control sample duplicates (LCS/LCSD). During the collection of field parameter data, precision was checked by reporting several measurements taken at one location and comparing the results.

Precision was evaluated on the basis of the relative percent difference between duplicate samples for a given analyte. RPD is calculated as follows:

$$RPD(\%) = \frac{C_1 - C_2}{(C_1 + C_2)/2} \; x\,100$$

where: RPD is relative percent difference, and
C_1 and C_2 are the results of replicate analyses.

A precision goal of RPD ≤ 30% was set for field duplicates for all analytes. For laboratory precision, the precision goal was 30% for organic analytes and 20% for other analytes.

F.2.3.2 Accuracy

Accuracy refers to the degree of difference between measured or calculated values and the true value. Accuracy was evaluated in terms of the percentage of a known amount of analyte or matrix spike recovered from a given matrix. Percent recovery for an analyte was calculated by:

$$\%\,R = \left(\frac{S - U}{C_{sa}}\right) \times 100$$

where: %R = percent recovery
S = measured concentration in spiked aliquot
U = measured concentration in unspiked aliquot
C_{sa} = actual concentration of spike added.

Accuracy was determined by the percentage of analyte recovered (%R) from the matrix spikes. Matrix spikes for laboratory analyses were prepared by injecting a known mass of a standard solution containing all of the analytes of interest into a groundwater sample, then analyzing the spiked sample according to the appropriate methods. Acceptable ranges for each analyte were as determined by the contract laboratory standard procedure.

The accuracy of field procedures is difficult to assess quantitatively. However, sampling accuracy was maximized by following standard protocols. Equipment and instrumentation was properly calibrated and well-maintained. Trip blanks were included in each sample batch to provide representative data to assess the potential for cross-contamination.

F.2.3.3 Representativeness

Representativeness is the degree to which a sample or group of samples accurately and precisely represents the population being studied. Over the course of this DEM/VAL study, samples were collected in a manner such that they represent both the chemical composition and the physical state of the sample in the groundwater at the time of sampling. Groundwater samples were not collected until field parameter measurements of the purged water had stabilized (generally within the following limits: temperature ± 0.2 °C, pH ± 0.2 standard units, specific conductance ± 5% of reading, DO ± 0.2 mg/L or 10%, whichever was greater, and turbidity ± 5 NTU or 10%, whichever was greater). The sample collection protocol minimized contact with the atmosphere to minimize volatilization.

F.2.3.4 Completeness

Completeness refers to the percentage of valid data received based on completed analysis performed in the laboratory, and is calculated by:

$$\%\,C = \left(\frac{V}{T}\right) \times 100$$

where: %C = percent completeness
V = number of measurements judged valid
T = total number of measurements

The completeness goal was to generate sufficient usable data to assess the technology performance. This was achieved, since all measurements were judged valid and no data were rejected.

F.2.3.5 Comparability

Comparability is the degree to which one data set can be compared to another. To optimize comparability, EPA established methods and approved protocols were selected or specified as appropriate for this DEM/VAL. To ensure comparability, samples were collected at specified intervals and in a similar manner, and were analyzed within required holding times by accepted methods.

F.2.3.6 Sensitivity

Sensitivity refers to the minimum magnitude at which analytical methods can resolve quantitative differences among sample concentrations. The sensitivity of an analytical method is expressed as the method detection limit (MDL), a theoretical concentration limit determined through an MDL study, in which the concentration of a spiked solution is tested at least 7 times. The standard deviation of the recovered concentrations (σ_{rec}) is computed and multiplied by the Student's t-distribution value to arrive at the MDL. In practice, to allow for matrix interferences and variability in instrument control, a reporting limit of 2.5 to 5 times the MDL is typically selected.

The MDL for all measurements is calculated according to:

$$MDL = t_{(n-1,1-\alpha=0.99)} \times s$$

where: s = standard deviation of replicate analyses of matrix spikes with concentrations near the MDL

$t\,(n\text{-}1,\ 1\text{-}\alpha = 0.99)$ = Students' t value for a one-sided, 99% confidence level and a standard deviation estimate with n-1 degrees of freedom.

F.3 DECONTAMINATION PROCEDURES

All sampling and field equipment received routine testing, inspection and maintenance checks to minimize equipment breakdown and ensure proper function. Routine daily maintenance conducted in the field included:

- Remove surface dirt and debris from the exposed surfaces of all equipment;
- Store equipment away from the elements;
- Inspect equipment and instruments for possible problems daily, including cracked or clogged lines or tubing, weak batteries, and worn pump heads; and

- Charge any equipment battery packs when not in use.

Cleaning of non-dedicated and non-disposable field sampling and measuring equipment and personal protective equipment (PPE) was performed to minimize the potential for cross-contamination between sample locations and samples, and to minimize the potential for exposure of workers to Site-related chemicals. All sampling devices and reusable PPE were decontaminated immediately after each use with direct application of a phosphate-free soap solution (i.e. Alconox™), followed by rinsing with distilled water. Expended decontamination fluids were containerized by the sampling personnel for disposal by NASA. Non-reusable sampling equipment, gloves, and tubing were disposed of appropriately following each sampling event.

F.4 SAMPLE DOCUMENTATION

Data management involved maintaining and controlling field data, laboratory analytical data, and any other data relevant to the project. Field data was recorded on designated forms or logs. Data entries included date and time. Sample collection data as well as visual observations were documented on specific forms and/or daily field notes. The sample collection equipment and field instruments were identified in the field documentation. Calculations, results, equipment usage, maintenance, repair and calibration data for field sampling, and field analytical and field physical measurement equipment was also recorded in field documentation. Once completed, the field forms were incorporated into the project file.

Sample collection and sample custody procedures were designed to ensure that custody of field samples was maintained and documented. These procedures provide identification and documentation of the sampling event and the sample chain-of-custody from shipment of sample bottleware, through sample collection, to receipt of the sample by the subcontracted laboratory. When used in conjunction with the laboratory's custody procedures and the sample bottleware documentation, these data establish full legal custody and allow complete tracking of a sample from preparation and receipt of sample bottleware to sample collection, preservation, and shipping through laboratory receipt, sample analysis and data validation.

A sample was in custody if:

- it was in the field investigator's, transferee's, or lab technician's actual possession; or
- it was the field investigator's, transferee's, or lab technician's view, after being in his/her physical possession; or
